As a corollary, advocates for intelligent robots believe without doubt that such machines will be “alive.” Various definitions for life exist, and most commentators consider it base chauvinism to deny that robots could possess it. By necessity, many advocates of machine intelligence, such as Hans Moravec and Ray Kurzweil, claim that biological life is evolving into machine life (Kurzweil 2005; Moravec 1988).

The desire to build artificial life was not born in the twentieth century; rather, robotics and AI extend a millennia-long exercise deeply tied to religious thought and practice. Particularly in the West, religious groups have looked upon the creation of life as the ultimate in *imitatio dei* (imitation of God), a tradition that extends across Judaism, Islam, and Christianity (though with more ambivalence in this last). In Judaism, for example, stories of learned and holy rabbis creating ► [Golems](#) trace back to the Babylonian Talmud, and were adapted into the legends of two early modern rabbis: Elijah of Chelm (d. 1543) and Judah Loew of Prague (1525–1609). Across the same time span, Muslims and Christians developed parallel and intertwined practices, mostly revolving around the creation of an ► [homunculus](#), which is a magical creature, usually but not always humanoid (though smaller), produced through existed in classical Islam and in medieval Europe. Theories of the homunculus both influenced and were influenced by those of golems. Jābir ibn Hayyān (c. 721–815), known as both the father of chemistry and the “Paracelsus of the Arabs,” believed that basic elements could be manipulated and balanced to produce life. His descriptions of the ► [homunculus](#) influenced later Islamic works, such as the *Book of the Cow*, and also alchemists in Christian Europe, such as the aforementioned Paracelsus (1493–1541). Unlike Paracelsus and the alchemists, the early modern rabbis almost certainly did not attempt to produce ► [Golems](#), yet the politics of the eighteenth- through the twentieth-century Europe led Jews to develop and sustain legends of ► [Golems](#) who could

save them from persecution, and these stories subsequently had a significant impact on the twentieth-century culture, from silent films to science fiction.

Early in the robotics era, science fiction authors imagined ways in which robots might participate in the religious traditions of humankind, with a range that includes developing their own religious sensitivities. Isaac Asimov, for example, has had an extraordinary influence upon robotics, and many contemporary roboticists continue to cite his stories as inspirational in their career choices. In his collection of robot stories, *I, Robot*, Asimov uses religious themes to help explore robotic potential, as when one group of robots establishes a religion that mimics the fundamental tenets of Islam, though applied to machines. Whereas Muslims aver that “there is no God but God, and Muhammad is his messenger,” the robots in Asimov’s story “Reason” claim that “there is no Master but the Master, and QT-1 is his prophet.” In this transmutation, a space station is the Master, and QT-1 is the robot who first began to worship it rather than obey its human creators. While Asimov uses religion to write a story about the operating possibilities of robots, other authors have used robots in order to explore religious themes, such as Clifford Simak, whose *Project Pope* describes human beings and robots collaborating in an attempt to produce a universal religion. The intersection between religion and robotics is not confined to science fiction, however, but has been a crucial element in popular explorations into the potential of robotics research and predictions about the future of the world.

Critical engagement between robotics and religion began in earnest with the publication of Hans Moravec’s *Mind Children: The Future of Robot and Human Intelligence* in 1988. In *Mind Children*, Moravec argues that Moore’s Law and the pace of improvements in computer vision indicate that robots are gaining intelligence at an exponential rate, which means that robots will reach human level intelligence in the near future before sailing rapidly beyond that level. As robotic technologies improve, Moravec argues, we will solve human handicaps and eventually

copy our personalities into robotic bodies. Ray Kurzweil, a prolific and famous inventor, extended Moravec’s ideas in *The Age of Spiritual Machines* (1999) and *The Singularity Is Near* (2005), presenting them to a wider audience and supplementing them with insights from nanotechnology and other technical fields.

In Moravec’s apocalyptic vision of our robotic future, nature values technology over biology. This latter has evolved specifically to produce the former, and will eventually be transformed into it. There is nothing “unnatural” about artificial intelligence, as technology is perceived to be an inevitable outcome of biological intelligence, and machine intelligence is taken as inevitable once technology has become widespread.

Historical time, in this apocalyptic vision of robotics, progresses indefatigably toward the Mind Fire (Moravec’s term) when computation has taken over all material reality. According to Moravec, evolution guarantees that the superior thinking of machines will outcompete that of humanity. Kurzweil argues that a law of accelerating returns guarantees that the world will experience a technological ► [singularity](#) in the first half of the twenty-first century. Subjective time is speeding up, he argues, and the coming decades will include unprecedented advances that will culminate in true artificial intelligence and the merger of biology and technology.

Moravec’s ideas spread, thanks particularly to Kurzweil, and thus commanded attention from theologians whose own desires were in conflict with Moravec’s. For obvious reasons, those who believe in immortal souls were never enamored with Moravec’s plan to provide immortality by “uploading” minds from bodies into machines. Were such a process possible, it would stand in the way of an individual’s ascent to Heaven; even faith that it *might* be possible could lead the faithful astray. It is not just theologians, but lay people who see ► [mind uploading](#) as a threat to traditional religions. Mind uploading is the hypothetical process of scanning the contents of a human brain onto a machine emulating a brain, so that human consciousness can continue in the machine. Kurzweil was featured in popular venues such as the *New York Times* and *Rolling*

Stone; as a consequence, some members of the Christian laity learned of his ideas and voiced their opposition (Tamatea 2010).

Despite the criticisms leveled against ► [mind uploading](#), many Christian theologians have seen value in robotics research, suggesting that it could either contribute to the establishment of a kingdom of God or that it could be an important continuation of divine creation (e.g., Foerst 2005; Jackelén 2002; Herzfeld 2002). On the one hand, research in robotics could provide important advances in human prosthetics, perhaps helping the blind to see and the lame to walk. In addition, some theologians believe that by creating intelligent robots, we will do so in our image, and hence in the image of God. Lutheran theologian Anne Foerst has developed this idea the furthest, arguing that, to be in the image of God means, fundamentally, to be in loving relations with others (as she believes that God is with humanity). As such, producing robotic friends and companions would expand the circle of love and contribute to the outflowing of divine love in creation.

Outside of Christianity, at least one community shares the belief that robots could become partners in human life. In Japan, the only non-Western community where the relationship between robotics and religion has received any attention, many people look forward to companionship between humanity and its mechanical progeny. Early in the introduction of robots to Japan, the public embraced them, even including them in religious practices (Hornyak 2006; Schodt 1988). Early industrial robots, for example, were welcomed into factories with Shinto rituals and gifts of flowers. As a number of individuals have recognized, the traditional acceptance that nonliving objects can be *kami* (loosely translated as having “holiness”), implies that robots can be *kami*. They can have spirit. At the same time, Japan’s other long-standing religious tradition, Buddhism, also provides room for the inclusion of machines. One engineer, Masahiro Mori, attained notoriety for his claim that robots have the Buddha nature in them (Mori [1981] 1999). Many Japanese cite their affection for and acceptance of robots as a consequence of their love of *Tetsuwan Atomu* (“Mighty Atom,”

known in the USA as “Astro Boy”). The cartoon robot never threatens humanity, as do many robots in the Western world; instead, he works to save us from harm. Broadly speaking, his influence, combined with the persistence of Shinto and Buddhist ideas in the largely agnostic country, promotes a spirit of cooperation and affection between human beings and robots. As a result, many Japanese eagerly look forward to the introduction of functioning, intelligent humanoid robots.

If robots become equal to humankind, there is a strong possibility that they might develop religious inclinations. Clearly, the standard questions of meaning, purpose, and ultimate origins will be as relevant to the robots as they are to human beings. Theologians like Foerst, along with a few computer scientists, such as Edmund Furse, believe that when robots become conscious, they will join our religious congregations or perhaps create religions of their own. Kurzweil claims that machines will be more “spiritual” than human beings, thanks to their superior thinking and powers of concentration. It is highly likely that developing religious sensitivities will, in fact, be closely intertwined with any social movement to provide legal rights to robots; if robots show a religious imagination, then they will go far toward entering human circles of empathy and earning themselves the rights and responsibilities of citizens; commensurately, a universal absence of religious feeling among robots would likely be taken as indicative that they are not and cannot be true persons (Geraci 2010).

At the same time, intelligent robots will without question have some kind of moral or ethical system by which to make decisions. From a human standpoint, it is impossible to separate questions of right and wrong from the matters of free will, consciousness, and personhood. As such, ethics will be as crucial as religion to any empathy directed toward intelligent machines (Geraci 2010). Should robots become intelligent, however, and acquire some set of ethics, they will have to do so while sailing between the twin dangers of the military and capitalism. These two institutions, like Scylla and Charybdis, could swallow up any good that we might hope

of our creations. Although Moravec believes that intelligent machines will be our “mind children,” and thus retain essential parts of our humanity, the science fiction author Charles Stross rightly points out that the majority of funding for artificial intelligence comes from military and economic strongholds, neither of which has any vested interest in developing altruistic and generous machines. As we continue to develop artificial intelligence, it behooves us to keep these concerns in mind, to ensure that if we truly can develop intelligent machines, then we will create machines worth befriending.

Both Moravec and Kurzweil, the leading figures at the intersection of religion and robotics, believe that advances in robotics and AI are morally good and will result in a morally beneficent universe. Both believe that as we merge with machines over the coming century, we will bring essential aspects of our humanity, including our good will and altruism. Technology should solve human problems, they argue, and both devote considerable time in their books to exploring how technology might solve our ecological crisis, provide renewable energy, improve food production and distribution, etc. In short, the merger of biology and technology will not only make human beings more capable, it will help us to overcome our past mistakes and create a better world.

It remains possible that, upon attaining human level equivalence, robots will rapidly progress to unimaginable heights of intelligence and power; if this happens, they may become as gods unto us. If this proves true, perhaps cyborg prostheses will permit humankind to match them in power, but this seems unlikely. After all, human bodies have limits to their size, mobility, and capacity. A robot freed from such constraints could – at least in theory – grow well beyond humanity. One AI theorist, Hugo de Garis, has gained some measure of infamy for his belief that such robots, which he labels “artilects,” will indeed become gods worthy of worship. While he recognizes that such divine machines may well find humanity an unnecessary burden or unacceptable competition, he believes this is a morally valuable outcome. That is, he has suggested that humanity may fight world wars over whether to build godlike

machines, or the machines might choose to exterminate many or all human beings, but that the successful construction of one divine robot will make all human suffering worthwhile. De Garis thus reconfigures ethics into an inhuman and possibly antihuman crusade for intelligent machines, where no other species has a claim to life, freedom, or happiness.

Moravec and Kurzweil, however, believe that humanity will join the godlike robots in their cosmic quest. In their apocalyptic predictions, the world will come to an end as we know it, and humanity will transform into a race of divine machines through ► [mind uploading](#) (Geraci 2010). Every advantage held by one of de Garis’s artilects will be shared by ex-humans; thus our immortal salvation will be assured. For Kurzweil, this outcome will be spiritual in addition to intellectual: First, as human beings add computational power, they will acquire new capacity for spiritual reflection; second, as the world, the solar system, and eventually the universe are converted to thinking entities, the universe will itself “wake up” and move inexorably toward traditional Christian conceptions of God.

There are rich areas for speculation in the intersection of religion and robots. While some hope that the construction of robots will fulfill long-standing religious goals, others expect that robotics will overthrow our traditional religions, producing either gods or substitute forms of salvation. Alongside all of this, the vast majority of professional roboticists have little or no investment in any of the varying intersections between robots and religion. Rapid growth and deployment of robotics throughout the world, however, means that the expectations of people on the ground – the scientific laity – should be more carefully explored. It is particularly important that researchers collect meaningful data from observations and interviews conducted among relevant populations, and not merely draw abstract conclusions on the basis of beliefs that the researchers presume people hold. The ethical implications of our current robots, such as weaponized military robots, certainly have religious overtones and should be examined through such a lens. In addition, we simply do not know enough

about how differing religious environments will affect either the development or use of robotic technologies. While research has begun in the Christian West, this remains largely abstract and broad, with little attention to the particulars of given Christian communities. More pressing, almost no research has been done outside of that context. There have been intriguing forays into Japanese practice, but more remains to be done in that area and, especially, beyond.

Robot Societies

Klaus Mainzer

[Artificial life](#); [Computer science](#); [Multi-robot systems](#)

A robot society is a group of robots which has the ability to communicate, interact, and to perform tasks jointly. A society is defined by its information and control structure which make possible common task planning and execution. Most of the autonomous mobile robots are operating in neither stable nor structured environments. Therefore, a major trend in robotics is going toward multi-robot systems. In many cases, the decomposition of a complex task into parallel subtasks is a possible way to speed up the performance. Sometimes, several robots work with the same subtask, increasing the redundancy of the system. Furthermore, there can be tasks where successful completion requires close cooperation among the robots. Such case is, for example, the carrying of a large object together. It requires some sort of interaction between robots, whether it is a direct communication or some sort of indirect communication through sensing the forces in the object to be transported. This kind of task as well as many other tasks normally related to multi-robot systems has clear analogy to biological systems. A group of ants solve the problem through sensing the forces and torque in the object. Based on this information they change the direction of force. Numerous similar examples can be found from nature. Tests by evolution during millions of years are proven to be feasible in dynamic and hostile environments and can thus provide valuable

information and inspiration for similar type of engineering tasks.

Artificial life represents an attempt to understand all life phenomena through reproduction in artificial systems, typically through their simulation on a computer. To attain this ambitious goal, artificial life relies on the theory of complex dynamical systems and on the power of computers. A complex dynamical system is a system that can be described at different levels, in which global properties at one level emerge from the interaction of a number of simple elements at lower levels. Global properties are emergent in the sense that they cannot be predicted from a knowledge of the elements or the rules by which the elements locally interact, given the high nonlinearity of these interactions (see the entry “► [Complex Systems](#)”). In engineering science, evolutionary robotics shares most of these characteristics with artificial life, but it also stresses the importance of using physical devices in robots instead of simulated agents.

Cooperative robots are constantly interacting not only with the dynamic environment, but also naturally with each other and with the persons who are using them. This large variety of interactions will produce behaviors that are going to be superior compared to performed by current single robots. The robots will be equipped to survive as a part of a complex system, where the cooperation is essential for their survival. Collective intelligence emerging from these interactions gives a reason to call these systems, at their highest level, “robot societies.” Multi-agent systems, whether software or hardware agent based, have to solve some fundamental problems. They must formulate, describe, decompose, and allocate tasks among a group of intelligent agents. Agents must be enabled to communicate and to interact. They must be ensured to act coherently in their actions. Further on, they must recognize and reconcile conflicts. Therefore, a model of distributed robotic systems must be defined and designed. All functions of these systems are obviously realized through their members. The members’ behaviors are results from their own needs and from the constraints set of the system, environment, or operator.

The number of distributed autonomous robotic system applications will increase as the

technology and knowledge improve. Various robot societies will move from research laboratories into everyday life. Normal applications concern everyday tasks like cleaning, monitoring, caring people in households or hospitals, etc. In the future, robot societies will be taken to distant planets, deep-sea module collection missions, and mining operations, among others. Nanosized robots will be sent into veins in search of tumors, which they will attack at close range. Just as in natural systems, the intelligence of the collective system will emerge from the multiple interactions among the members and with the environment.

In first steps of development, natural populations, for example, ant societies, were studied to find the key issues. Next steps were to design a physical society. It consists of two types of autonomous mobile robots, and the task for the society is classical, to gather stones from an unknown environment along with the mapping of the environment while operating. The society has been implemented both as a physical society and as a simulated one. A possible application is the use of a robot society inside industrial processes.

A profound challenge of interdisciplinary importance is the question how culture may emerge and evolve as a novel property in groups of social animals. The question can be solved by focusing the attention on the very early stages of the emergence and evolution of simple cultural artifacts. Therefore, one should start by building an artificial society of embodied intelligent agents as real robots, creating an environment or artificial ecosystems. Even with small populations of simple robots, a large number of interactions between robots can be generated. The inherent heterogeneities of real robots, and the noise and uncertainty of the real world, increase the space of possibilities and the scope for unexpected emergence in the interactions between robots.

The goal is to create the conditions in which proto-culture can emerge in a robot society. Robots can copy each other’s behaviors and select which behaviors to keep. Behaviors will mutate because of the noise and uncertainty in the real robots’ sensors and actuators. Successful types of behavior will undergo multiple cycles of copying (heredity), selection, and variation (mutation). With evolutionary

time, a genetic algorithmic process will grow and evolve the robots' controllers so that the emerging patterns of behavior become hard-wired into the robots' controllers.

The behavioral artifacts emerging and evolving will not be human but robotic. They will be meaningful only within the closed context of this artificial society. A significant challenge for these projects will be to identify and interpret these patterns of behavior as evidence for an emerging proto-culture.

Based on the economic ideas about cost and utility, robot ecosystems were developed. From an ethologist's point of view, robots are interesting for investigating biologically realistic issues. The emergence of cooperation can be studied by experiments with robots. For example, in a robot ecosystem, there are a few robots and a few boxes with infrared lamps. The lamps are called competitors because they (like robots) consume energy from the ecosystem. As the overall amount of electricity is limited, the robots have to compete with the lamps for the electricity. A constant but restricted influx of energy into the system limits the amount of electricity available. The robots have to push against the competitors to reduce the competitors' energy consumption.

Reducing the infrared lamps' energy consumption dims their lights. The darker the boxes, the more current there is in the charging station. The robots are equipped with the sensors whose activation levels can be coupled to motivations. If the environment is made more taxing by increasing the number of energy-consuming boxes, the robots have to exploit these sensors to produce beneficial sensor-to-motor couplings. Beneficial in this case means leading to higher available energy levels.

For example, the robots have a sensor for internal energy level. If the sensor is coupled directly with the motivation for forward movement, the robot moves more slowly when the energy is low, which makes the robot take longer to move through the charge station. The robots also have a sensor for detecting the charging station. If the sensor is inversely coupled to the motivation for forward movement, this keeps the robot in the charging station even longer. In addition, the robots have light sensors, and the

charging station is marked with a light, so they can potentially use phototaxis to approach the charging station. If the robots exploit the various sensory modalities in appropriate ways, they get an advantage in terms of energy management. This implies increasing the complexity of their behavioral repertoire, for example, better exploitation of the motor system.

When an evolutionary perspective is applied, one needs a value system. In the robot's case, it is related to energy supply: Increase in energy level is of value. The task of energy management is difficult, because the beneficial effects of certain actions manifest themselves only much later. This is a fundamental issue in reinforcement learning. The entire experiment can also be put into an evolutionary context. It would be interesting to study what sorts of value systems would evolve.

Cooperation can also be studied in this experiment. The energy influx into the charging station increases if another robot pushes against the energy-consuming boxes. In a sense, the robot that pushes against the boxes works for the one in the charging station. If the robots cooperate in this way, they can potentially draw more current from the charging station. Thus, they may be able to support more robots, because they manage to divert electricity from the competitors. This entire procedure can also be embedded into an evolutionary cycle. In this case, one can see which sensors will be exploited, given a particular environmental pressure. The fitness criterion in this case would be: How long the agents can survive?

The behavioral economics approach to autonomous agents brings in important ideas. Thinking in terms of utilities rather than specific quantities leads to plausible models of rational behavior. This framework is highly useful in understanding animal behavior and behavior of autonomous agents in general. The idea that rational behavior can occur *without* rational thinking or that the problems of thresholds can be avoided by using utilities is highly appealing. The fact that behavior is an emergent property of the interaction between robots and their environment has the consequence that simple robots can produce

complex behavior. However, it also has the consequence that, as in most dynamical systems, the properties of the emergent behavior cannot easily be predicted or inferred from the knowledge of the rules governing the interactions. The reverse is also true: It is difficult to predict which rules will produce a given behavior, since the behavior is the emergent result of the dynamical interaction between the robots and the environment.

However, the behavioral economics approach has some problems. The main drawback of behavioral economics is that the approach is more analytical than synthetic. It does not provide heuristics on how to derive the mechanisms that lead to the desired behaviors. Another difficulty is that the approach is top-down and suggests that careful prior analysis of the problem can produce optimal designs. Experience with software engineering suggests that a top-down approach may not work well in an unstructured domain. Moreover, from a cognitive science perspective, a bottom-up approach seems more promising.

College, Mount Berry, GA, USA

An visible sign of the grace given by God and communicated to humans through participation in Christ's body – that is, the life of the church. Catholic and Orthodox churches accept seven sacraments: baptism, Eucharist, confirmation, penance, extreme unction, ordination, and marriage. While the sacraments of baptism and Eucharist are accepted by almost all Christian churches, Protestant churches generally do not recognize the latter five. Throughout history, sacraments have been integrally bound up with the spirituality of Christian individuals and communities.

[Mental disorder](#)

Description

Schizophrenia is a severe and complex mental disorder that affects about 24 million people worldwide. Due to chronification, the prevalence ($\sim 0.7\%$) substantially exceeds its rather low incidence ($\sim 0.03\%$). Symptoms, which typically begin in late adolescence or early adulthood, are multifaceted and include thought fragmentation or disruption, delusions and hallucinations (“positive symptoms”), as well as cognitive deficits, poverty of speech, emotional blunting, anhedonia or the lack of interest in or pleasure from activities usually found enjoyable, lack of motivation, poor grooming, and social withdrawal (“negative symptoms”). During its often lifelong course, schizophrenia can cause major disabilities in multiple spheres of an individual’s functioning such as activities of daily living, including self-care, and social and occupational competence.

Schizophrenia research is a subdiscipline of psychiatry. It has profoundly enhanced our understanding of this major psychiatric disease and has thus facilitated the development of increasingly effective forms of treatment. During the past decades, schizophrenia research has fostered a multitietologic, so-called biopsychosocial model of schizophrenia implying significant roles of genetic, environmental, psychological, and neurodevelopmental factors for both origin and trajectory of the disease. As a consequence, treatment strategies have been developed that in many cases already enable affected people to lead a productive life and to be integrated into society. Current developments in the field comprise:

Pathogenesis

Most recently, several genetic variants have been identified that may predispose the brain to developing schizophrenia (“susceptibility genes”). Researchers hope that replication of disease-associated genetic variants across multiple cohorts in large-scale studies may pave the way toward novel gene-based therapies (Kim et al. 2011). Other avenues of current research on schizophrenia etiology follow the evidence that schizophrenia shares aberrant

neurodevelopmental and even neurodegenerative features (Powell 2010).

Diagnosis

Recent interest has focused on the identification of preclinical disease stages in at-risk populations with the intention to discover early intervention strategies. To this end, disease biomarkers are being developed using molecular genetics, cerebrospinal fluid-based markers, structural and functional neuroimaging and, most recently, combinations thereof, e.g., imaging genetics (Oertel-Knöchel et al. 2011).

Treatment

Whereas previous and current pharmacological treatment strategies largely center on the so-called dopamine hypothesis as a specific biochemical dysregulation hypothesis in schizophrenia, ongoing drug research involves different neurotransmitter systems such as the glutamate and serotonin system.

Disease Concept

It has increasingly become clear that schizophrenia is not a single disease entity, bearing rather heterogeneous etiological factors, pathophysiological mechanisms, and clinical manifestations. Thus, on the current road to new diagnostic classifications in psychiatry (Diagnostic and Statistical Manual of Mental Disorders, 5th revision), efforts have been made to deconstruct schizophrenia as an entity into component dimensions linked to unique etiological and pathophysiological processes that may yield unique treatment targets (Nasrallah et al. 2011).

Self-identification

Science

Schizophrenia research is a biomedical, psychosocial, and anthropological science. It is a subdiscipline of *psychiatry* using molecular biological, biochemical, genetic, and neuroimaging as well as psychological and socio-epidemiological methods, among many others. It generates hypotheses and theories that are constantly being

reviewed, modified, and rejected. Research on schizophrenia is a science in that it “builds and organizes knowledge in the form of testable explanations and predictions” (Science. <http://en.wikipedia.org/wiki/Science>) about its specific topic, schizophrenia.

Characteristics

Schizophrenia as a disease may, unlike other diseases, lead to profound impairment of the perception of the environment (external reality) and the affected individual’s self (internal reality) to an extreme extent due to core symptoms such as delusions, hallucinations, and symptoms the German psychopathology refers to as “*Ich-Störungen*” (particular delusions that one’s thoughts are controlled, inserted, or withdrawn by external force).

Schizophrenia research as a scientific subdiscipline of psychiatry is distinctive among other disciplines/subdisciplines in its profound and almost unique overlap of natural sciences and humanities pertaining to methods and content of research. It integrates a diverse array of scientific disciplines such as but not confined to biomedicine, molecular biology, biochemistry, psychology, anthropology, social sciences, and philosophy.

Relevance to Science and Religion

Although still not fully considered in psychiatric and specifically in *schizophrenia research* numerous relations exist between *schizophrenia* and religion in its broadest sense (from spirituality to religiousness). The impact of religion on schizophrenia “... ranges from the worst to the best, as we can observe in the history of religion in mankind” (Mohr and Huguelet 2004). It may be positive (in helping to cope with the illness) or negative (in leading to violent behavior and refusal of treatment due to religious delusions). The significance of the schizophrenia–religion relationship is shortly exemplified by the following paragraphs.

Religious Delusions in Schizophrenia

Religious content is common in schizophrenic delusions and hallucinations. Such symptoms tend to be persecutory and may lead to acts of violence against oneself or others, e.g., in the perceived need of defense (against the devil, demons, etc.). Also, delusions of grandiosity (being god or sent by him) and belittlement (unforgivable sinner, etc.) occur frequently. There is a certain diversity of such psychopathology across different cultures. It has to be considered, though, that a continuum exists from religious beliefs to religious psychopathology and that the Western medical model tends to emphasize pathology over traditions (Mohr and Huguelet 2004).

Religious Coping in Schizophrenia

Religious commitment has been related to lower rates of suicides in individuals with schizophrenia (Koenig et al. 1998). Psychotic individuals often use religion to cope with their devastating symptoms and so do families in support of their ill relatives (Rammohan et al. 2002). Coping strategies include spiritual and congregational support (help by god, a priest, etc.), religious reframing (hallucinations being a godly test, etc.), and generally religion as guidance through psychotic anxiety and terror.

Religion, Spirituality, and Individual Outcome in Schizophrenia

Spirituality as an individual resource may play a crucial role in the heterogeneity of outcomes in this disease. Religious beliefs in individuals affected by schizophrenia may come with certain identification models strengthened by the active support of the religious community which may lead to a beneficial outcome. Other individuals may be burdened and demoralized by their religious beliefs or that of others (Mohr and Huguelet 2004).

Sources of Authority

The German psychiatrist Emil Kraepelin (1856–1926) distinguished individuals suffering from hallucinations and delusions and

a long-term dementia-like deteriorating course with early onset from those classified as having episodic manic-depressive psychosis with intermediate periods of normal functioning. Eugen Bleuler (1857–1939) from Switzerland coined the term “schizophrenia” (Greek: σχιζεῖν = “to split,” φρεν = “mind”) denoting the intrapersonal and personal-environmental schisms typically occurring with the disease. The term has been internationally accepted but has led to the common misconception of a “split personality” and confusion with a condition today known as Dissociative Identity Disorder. Kurt Schneider (1887–1967) described a set of characteristic psychopathological symptoms that may guide the diagnostic process (such as audible thoughts, hearing of commenting voices, delusional perceptions, etc.). Psychopathological considerations of the named and of other famous psychiatrists have been incorporated into modern major diagnostic classification systems.

Ethical Principles

Ethical key concerns in modern management of and research on schizophrenia mainly focus on the issues of the disease-inherent impairment of the decision-making capacity and capability to give informed consent to treatment and/or scientific investigation. Regarding therapeutic decisions, the personal freedom of a given subject to refuse treatment or restraint has to be weighed against potential risks when treatment or restraint is not being installed (violence, suicidality, etc.). Regarding research studies, the risks of exposing schizophrenia patients as particularly vulnerable subjects to new forms of treatment has to be weighed against the benefit for future generations of those affected. Ethical principles that apply to treatment and research on schizophrenia are laid down in the Nuremberg Code, the Declarations of Geneva and Helsinki, the so-called Beecher Paper, the Protocol of the International Committee of Journal Editors (aka “Vancouver Group”), and the “Belmont Report” (Fischer 2006).

Key Values

Key values of *schizophrenia research* are the ethical principles as stated above, the guidelines of Good Clinical Practice (GCP) and Good Laboratory Practice (GLP), and the principles of evidence-based medicine.

Conceptualization

Nature/World

Nature is the physical/material foundation of life. Diseases such as schizophrenia are dysfunctional implementations of nature. Schizophrenia research is thus to a large extent a natural science.

Human Being

Schizophrenia affects the human being as a whole in that it fundamentally interferes with its perception of and reflection on the world and consequently impairs the affected individual’s interaction with his or her environment.

Life and Death

Schizophrenia as a mental disease is an abnormal condition of life that leads to functional impairment of the affected individual, to suffering, and often premature death.

Reality

Reality is in a very basic sense the state of things as they appear to the (human) observer based on multisensory perception. Severe impairment of sensory information processing in schizophrenia often drastically impairs an individual’s sense of reality causing misinterpretation of situations and events.

Knowledge

Schizophrenia research is building systematic knowledge of its specific field out of information gained by observation and the testing of hypotheses and applies it in order to broaden its understanding of how the disease develops, proceeds, and how it can be treated.

Truth

Truth in the context of schizophrenia research is the outcome of evidence-based scientific investigations.

Perception

Experimental studies with schizophrenic individuals have provided evidence for a profound disturbance of sensory processing, e.g., visual stimuli. Patients with schizophrenia seem to experience a rather random and fragmented than continuous sensory input pattern. This lack of consistency of sensory input may contribute substantially to the disintegration of reality which in turn leads to feelings of confusion, anxiety, and delusional states.

Time

Among other fundamental perceptual deficits, alterations of the subjective experience of temporal relations and the orderly temporal integration of internal and external information has been consistently demonstrated in individuals with schizophrenia most probably due to the impairment of various sensory input mechanisms. This perpetuates the individual's feelings of isolation and distress and may contribute to the loss of social cognition since time represents social order in daily life.

Consciousness

The symptoms of schizophrenia have been explained to emerge from an abnormal permeability of the consciousness due to impairment of the mechanism that controls and limits the contents of consciousness. As a consequence, excessive self-awareness and thinking may occur and account at least for some key aspects of "positive symptoms" and cognitive abnormality.

Rationality/Reason

Reason/rationality as the capacity of human beings to explain and make sense of things and situations in the world is largely dependent on perception and its processing in the brain which is fundamentally impaired in schizophrenia.

Mystery

Mystical experience/mystery in the sense of irrational presumptions of the world is a frequent topic in the schizophrenic perspective of reality.

Relevant Themes

Since culture is highly intertwined with religion, the cultural background is important when dealing with the issue of "Science and Religion," also in the context of schizophrenia treatment and research. Interdisciplinary cross-cultural research is beginning to elucidate how socio-environmental and cultural variables interfere with physiological pathways and genetic constitutions that relate psychosocial stress and psychotic symptomatology (Howes and Kapur 2009). Such knowledge could lead us to understand how culturally available tools such as religious practices may mitigate the disease burden and to design effective interventions for individuals with schizophrenia (Myers 2011).

Introduction

Jewish mysticism has a complex history through which various distinct phases have been identified.

The principal source for all mystical speculation in Judaism is the *Torah* and other texts from the Hebrew Scriptures. From this perspective, the origins of the Jewish mystical tradition lie in the distant past. The earliest overtly mystical works in Judaism date from the third to sixth centuries CE and treat of the “secrets” of creation and the experiences of those who explored “heavenly” realms. While this, and each subsequent, phase has its defining characteristics, there are core features which enable us to identify the generic form of Jewish mysticism. Jewish mystics believe that the Torah contains an inner wisdom transmitted from God, which treats of the nature of ultimate reality. The mystical tradition conveys knowledge of the inner workings of the Godhead, which are recapitulated in all of creation. The tradition also conveys certain details of the practices whereby mystics may aspire to a higher state of being in which closeness, or even union, with the divine is experienced.

In this article, I shall use the term “Kabbalah” to refer generically to Jewish mysticism. There is a degree of ambiguity about the term, for some apply it specifically to the traditions stemming from the creative period of the twelfth and thirteenth centuries in Southern France and Spain, while others use it to cover the entirety of the mystical core in Judaism. While we do not find the term *Kabbalah*, nor the related *mekubbalim* (“kabbalists”) prior to the twelfth century, the kabbalists in later periods certainly saw themselves as heirs to a coherent body of esoteric knowledge that constitutes the backbone of the Jewish tradition. The Hebrew root of the term “Kabbalah” means to “receive” and comes to designate the *received tradition*. In part, this reflects the notion that kabbalistic teachings had to be received orally from a teacher, but there is the further connotation that kabbalistic practices bring the individual into a deep relationship with the divine, or an agent of the divine, who imparts knowledge in a direct encounter.

The relationships between the discoveries of modern science and the insights found in the kabbalistic tradition require more than a cursory examination of both spheres. In the first place, Kabbalah is essentially concerned with the *spiritual* world, while science explores the realm of

the *physical*. A simple analysis would accordingly conclude that there can be little direct rapport between the two endeavors. As my explorations in this article will suggest, such a view is too monolithic and fails to capture the subtleties in both domains. Despite the seeming irreconcilability between their respective orientations, both Kabbalah and science are directed to uncovering the deeper structures and processes that underlie our experience of the world. While Kabbalah is essentially concerned with knowledge of God – which *prima facie* sets it apart from science – its path necessitates grasping the patterns that confront us in the outer world and in the inner realm of thought. The analysis of these physical and psychological domains is clearly within the remit of science; the question is, do the insights from the two traditions connect in any way?

A second reason for the need to dig beyond a simple understanding of Kabbalah and science arises from the dynamic nature of each. What exactly constitutes science is not an easy question to answer, and many have argued that challenges in areas like the fundamental constituents of matter, and the nature of consciousness are stretching the bounds of science as classically understood. As for Kabbalah, its language is highly codified. Indeed, becoming familiar with the elaborate system of symbols and codes constitutes an initiatory challenge for the would-be kabbalist. Moreover, its teachings have been limited by the worldview of their day. These writings hardly bring their scientific implications to the fore. Accordingly, some explication and elaboration of the original texts will be necessary in order to juxtapose Kabbalah and science.

Levels in Mind and Outer Reality

Kabbalah may be aligned with the view expressed by many quantum physicists that no rigid demarcation exists between mind and physical reality. A classical statement to this effect comes from Eddington: “The universe is of the nature of a thought or sensation in a universal Mind.” Similarly, de Broglie and Wigner, both pioneers of quantum mechanics, held that

consciousness is intrinsic to the quantum worldview. These ideas derive from the seemingly “mental” properties of elementary particles in the ways they interact and from the role observation plays in the collapse of the wave function. The quantum principle of nonlocality, for example, implies that something akin to *knowing* characterizes the behavior of micro-entities at a distance. In a recent overview of quantum phenomena, Schäfer (1997) asserts that “It is now possible to believe that the mind is the realization of *potentia*, a manifestation of the essence of the universe.”

In common with other mystical and spiritual traditions, Kabbalah views the universe in mentalist terms, which dovetail with these views deriving from quantum science. The universe is held to be the product of thought – divine thought and is maintained by God’s thought day-by-day. Moreover, a profound correspondence is said to exist between the universe and the human mind. The major text of Kabbalah, the *Zohar* (Margoliot 1978), states that the “artistry and design of the human being resemble the world” (*Zohar* 1:90b). Such statements – deriving ultimately from the biblical maxim that humankind is created “in the image of God” – apply only superficially to the physical human form: “The human soul is known . . . through the organs of the body” (*Zohar* 1:103b). It is the human soul, or mind, that is seen to be paralleled in the universe.

A central tenet of Kabbalah is that God is knowable through His emanations, termed *sefirot*, and that all things – both in the universe and in the mind – derive from the pattern of these emanations, known as the “tree” of the *sefirot*. The *Bahir*, a twelfth-century work expresses the point emphatically: “[God says,] I am the one who has planted this Tree for the whole world to enjoy. In it I spread the totality of all-that-is, and I called its name ‘All’ For All depends upon it and All goes forth from it and All need it.” (Abrams 1994).

In this sense of the *potentia* (to use Schäfer’s Aristotelian word), then, Kabbalah holds there to be no disjunction between mind and cosmos. In the words of the thirteenth-century Moses de León: “[God] created man in His pattern, in the

image of the likeness of His form. In miniature, he comprises the form of the world, which is in the image of the [sefirotic] entities.”(Moses 1988).

The fundamental pattern is discernible *par excellence* in the Torah, which – far from being merely a *book* – is effectively the *world soul*, the living essence of reality. This essence unfolds characteristically through a dance of *concealing and revealing*: “Throughout the entire Torah, we find that the revealed coexists with the concealed. So it is with the world, both this world and the higher world, everything is concealed and revealed” (*Zohar* 2:230b). Moreover “Each domain comprises level upon level, concealed and revealed” (*Zohar* 3:73a). The challenge to unearth level upon level of meaning in the Torah very much comprises the heart of Judaism. To the extent that an interpretation is “concealed” prior to its being “revealed,” the Torah can be seen to exemplify the cosmic pattern underlying all things. It is the bold assertion that *everything* manifests according to this dance of concealing-revealing that epitomizes the kabbalistic worldview. Parallels with physics and psychology are striking: quantum physics describes a similar “dance” whereby the elements of reality are continually unfolding (becoming “revealed”) from, and being reabsorbed into, the “concealed” matrix, according to whether they are observed or not, and depth psychology conceptualizes the impact of events on the life of the unconscious and the movement of thought from unconscious (“concealed”) to conscious (“revealed”).

Multiplicity and Holism in Science and Kabbalah

These parallels across Kabbalah, quantum physics, and depth psychology extend into the way we might characterize the concealed and revealed levels. The concealed level is multipotential, holographic, and infinite; the revealed is particular, discrete, and finite.

For Kabbalah, the holographic nature of the concealed is given expression in its view of the Torah, the inception of creation, and those events or entities which express contact with the

transcendent. The Torah is identified with the divine. Accordingly, just as God is infinite, so must the Torah be infinite (Idel 2002). Indeed, according to the eighteenth-century Luzzatto, every one of its letters is infinite. All the elements of the Torah – its stories and laws, each word, and every letter – can unfold into an infinite number of interpretations: “There is not a single word in the Torah that does not radiate many lights in every direction” (*Zohar* 3:202a). A division is made between what may be conceptualized as the *primordial* Torah and the regular Torah that is written on the parchment scroll. The former is written in “black fire on white fire” and constitutes the plan of all-that-is. It comprises the name of God – which, for Kabbalah means the very essence of God – in infinite permutations. The concrete Torah might be best conceptualized as the intermediary vehicle between the ultimate, and infinite, primordial Torah and the Torah existing in the minds of those who study it, where there are a fixed, finite set of interpretations. In a more complex formulation, deriving from the Lurianic school of Kabbalah in the seventeenth century, the individual soul only comes into being as a result of the specific form of interpretation that is particular to it. The soul’s very existence is dependent on the way the Torah will be *observed* by that person – a formulation reminiscent of the quantum view of the role of observation in collapsing the probabilistic wave function and bringing a discrete entity into existence.

During the primordial inception of creation, “All things were contained one within the other, good inclination and evil inclination, right and left, Israel and the nations, and white and black. All things were dependent on one another” (*Zohar* 3:80b). A further insight into the kabbalistic view of the very beginning of creation comes with the seminal idea that the Hebrew letters are the agents of the creative process. Thus, the first letter, *Alef*, itself a silent letter, epitomizes the primordial beginning – a nothingness and, at the same time, the totality that lies behind the beginning of manifestation (in turn symbolized by the second letter, *Bet*). “At the beginning of all is *Alef*, beginning and end of all the levels . . . designated as ‘one’

to indicate that, even though it contains multiple images, it itself is undivided unity” (*Zohar* 1:21a).

The letter *Alef* begins the biblical enunciation of the *Ten Commandments* and is taken as a hint that the voice which resounded forth at Mt. Sinai was itself holographic and that each soul present experienced it in a way dependent on its individual propensity. As recorded in the Bible itself, the experience was synesthetic (“and all the people saw the voices,” *Exodus* 20:18), implying a transcendence of the specificity of the senses. “All that they saw . . . they saw in one light which encompassed all the other lights” (*Zohar* 2: 146a).

These examples epitomize the view, expressed already in rabbinic Judaism and much elaborated in Kabbalah, that the concealed, inner level is holographic in form. A number of scientists have been led to similar views through their understanding of the findings of quantum mechanics. Bohm (1980) postulates the existence of two orders of reality, one *implicate*, the other *explicate*. The implicate order is the hidden basis from which all things arise; it is characterized as holistic such that “everything is enfolded into everything.” The explicate order, by comparison, comprises entities which are each located in their particular time and space. The concealing-revealing paradigm in Kabbalah is paralleled in Bohm’s model by the *enfolding* and *unfolding* which he sees as characterizing the movement from explicate to implicate levels and vice versa. In a formulation that tightly parallels the kabbalistic emphasis, Bohm asserts that this movement – the *holomovement*, as he calls – is the ultimate reality.

Schäfer infers from the data of quantum physics that reality comprises two domains: the “outer” domain includes the material things of immediate experience, while the “inner” is hidden, has the nature of undivided wholeness, and consists of “nonmaterial, nonempirical forms.” These nonmaterial forms are real inasmuch as they manifest themselves in the empirical world and act in it. Schäfer’s description of the concealed realm could be applied verbatim to Kabbalah’s view of the realm of the *sefirot*. The *sefirot* are holonomic in the sense that each is present in all others, and they constitute the

hidden pattern that is manifest in the world to those who quest to see it:

Although [the *sefirot*] are supernal mysteries that cannot be known to the worlds, their influence and effect pour down and extend to the lower world; as a result of this extension, we in this world can have perfect faith . . . in those levels, as if they were revealed, and were not hidden and concealed. *Zohar* 2:137a.

A final idea which should be included in a consideration of notions of multiplicity in science and Kabbalah is that of the “multiverse.” The notion that our universe is just one of many parallel universes has been advanced in both quantum mechanics and astrophysics. In brief, the “many worlds” hypothesis suggests that collapse of the wave function (i.e., the actualization of observable situations from the preobserved potentia) gives rise to multiple alternatives, each of which is realized in a different world. Given the large number of possibilities thus arising moment-by-moment, the overall effect of this hypothesis would be a near-infinite proliferation of worlds. Astrophysicists arrive at a similar conclusion from the *anthropic principle*; the odds against the Big Bang giving rise to the right set of circumstances for a universe conducive to life to arise are so astronomical that we must assume that ours is only one of many universes.

An echo of the concept of the multiverse is found in Kabbalah in its notion that ours is not the only universe which has been created. In early kabbalistic literature, the other creations are seen as *prior*, not parallel, worlds, a view which perhaps attenuates the link to astrophysics somewhat. Kabbalistic thinking comes closer to the many worlds hypothesis in its understanding of the infinite number of interpretations of the Torah which exist each in its own world. For the thirteenth-century Gikatilla, the diversity of interpretations of the Torah gives rise to “thousands and thousands of worlds,” and a seventeenth-century Lurianic text asserts that “just as there is an infinite number of worlds, so is the depth of the Torah infinite.”

Whatever the status of diverse worlds in its scheme of things, Kabbalah articulates its central tenet that God is the creator of all that exists

unambiguously. In this context, it is important to realize that the hypothesis of the multiverse is not the only solution to the anthropic conundrum: The alternative is to posit a creative intelligence which in some way *chose* the precise details of the Big Bang – effectively a Creator God. In this context, the interest of Kabbalah focuses on the primordial processes which unfolded prior to the events described in *Genesis*. The kabbalistic narrative of creation parallels the model advanced in astrophysics inasmuch as both describe the beginning as involving a tiny point of origin, which forms within a domain of “absence” and subsequently expands. For astrophysics, the Big Bang arises from an infinitesimally small, infinitely hot, and infinitely dense *singularity* inside a black hole. For the *Zohar*, the primal origin is “unknowable, concealed in recesses like the point of a needle” (1:21a). The Lurianic Kabbalah describes the initiating dynamic of creation as arising when God vacated a space within His all-enveloping oneness. The primordial polarity between His presence and His (relative) absence lies behind all of manifest creation. As Matt (1996) points out, the parallel here with the *quantum vacuum*, from which the explosive expansion of the Big Bang is posited to have arisen is striking.

The kabbalistic perspective on the origin of things returns us to our earlier emphasis on the oneness that comprises physical and mental realms, for the mystery of creation is “the mystery of the concealment of thought” (*Ibid*). “When the most concealed of all concealment sought to be revealed, He made first a single point, and this arose to become *thought*” (*Zohar* 1:2a). Here, we enter the enigma of consciousness. I shall consider two issues: Firstly, the extent to which kabbalistic insights relate to recent findings in the science of consciousness and, secondly, the relevance of Kabbalah to a psychological understanding of spiritual transformation.

On Consciousness and the Quest for Transformation

Whatever parallels we may find between the view of reality as presented by physics and that

intrinsic to religious and mystical systems, one crucial difference remains. Physics is necessarily silent on the potential value of the transformative path that the mystical systems describe. Describing a hidden order lying behind the everyday world of experience is not an end in itself for Kabbalah; rather knowing is the handmaiden of journeying. The mystic is enjoined to embark on a quest for the divine, to achieve self-perfection, and contribute to the ultimate task, namely, rectification of divine and human realms. To put it in terms of the hidden order mentioned above, the *sefirot* are not merely the nonmaterial forms that order our world, they constitute a two-way sequence between the Absolute “above” and mundane human consciousness “below.” From above to below, they describe the emanation of divine light through creation, and from below to above, they become the ladder of mystical ascent.

This disjunction between science and mysticism in terms of values and goals extends to the study of consciousness. A scientific account of consciousness attempts to specify the processes, most especially *brain* processes, that correlate with the presence of consciousness; neuroscience in particular has little to say about the value we might attribute to the kinds of higher states that mysticism fosters. In contrast, a kabbalistic account emphasizes the transformative dimension; it is interested in the relation between mundane states and expanded states of consciousness, between the ordinary state that it likens to sleep and “awakened” consciousness. And, of course, it sees the awakened, expanded state which brings closeness to God as a goal.

Despite this crucial difference in emphasis, there are significant points of comparison between what has been discovered about the brain correlates of consciousness and core kabbalistic teachings (Lancaster 2004). There are two key principles of the brain’s functioning which have been correlated with consciousness: *binding*, meaning the generation of coherence among assemblies of neurons, and *recurrent processing*, which refers to the impact of “descending” neural pathways on activity in “ascending” pathways. To put it simply, *conscious* mental activity only comes about when both of these features are

present; mental events are conscious when, and only when, large assemblies of neurons fire in coherent synchrony (binding) and the incoming neural activity has been modulated by the outflow of activity from the brain's higher centers (recurrent processing). The kabbalistic teachings to which these relate are those of *unification* and *reflexivity* respectively.

As far as the consonance between binding and unification is concerned, both involve harnessing diverse elements together by means of establishing coherence. In the brain, it is the coherence in oscillatory firing patterns between diverse groups of neurons that signals their integration. The analogy with kabbalistic teaching is that coherence across different levels in the created hierarchy is viewed as bringing about the highest mystical states:

"One" – to unify everything from there upwards as one; to raise the will to bind everything in a single bond; to raise the will in fear and love higher and higher as far as *En-Sof* [the limitless essence of God]. And not to let the will stray from all the levels and limbs but let it ascend with them all to make them adhere to each other, so that all shall be one bond with *En-Sof*. (*Zohar* 2:216b)

A major goal of all kabbalistic practice is to promote the unification of the divine name, a concept which focuses on binding the *sefirot* but extends more generally to include unifying all strands of thought and other mental processes.

Moving on to the fit between recurrent processing and reflexivity, both depend on activity at a "lower" level triggering activity in a "higher" level, which in turn acts back on the lower level bringing about the intended effect. In neuroscience, this system has been identified in relation to the brain's sensory processing systems, with the "lower" level comprising brain structures concerned with immediate properties of the sensory stimulus and the "higher" structures being those dealing with memory and cognitive analysis of the sensory signals. It appears that the *meaning* of the sensory stimulus is determined when the activity from the higher centers impacts on the lower regions though recurrent processing. The indispensability of recurrent

processing for consciousness cannot be overstated. Indeed, there is compelling evidence that it is the "key neural ingredient of consciousness," according to Lamme, a neuroscientist studying the brain and conscious states.

The analogous teachings in Kabbalah need some unpacking from their context in order that the parallel with these findings in neuroscience might become evident. The *Zohar* enunciates the core teaching in its poetic language:

Come and see. Through the impulse from below is awakened an impulse above, and through the impulse from above there is awakened a yet higher impulse, until the impulse reaches the place where the lamp is to be lit and it is lit . . . and all the worlds receive blessing from it. (*Zohar* 1: 244a)

The central imagery of the Kabbalah focuses on the *sefirotic* realms existing between the mundane human sphere and the Absolute. In this scheme, the "impulse from below" arises through prayer or other spiritual work and brings about resonances throughout the successive intermediary realms reaching to the top of the *sefirotic* chain. The "lamp" refers to an aspect of the Godhead which is capable of bestowing the "divine" influx or "blessings" back into the human sphere. Clearly, the imagery of the lamp being "lit" equates to the activation of this higher aspect of the Godhead.

We see here the fundamental operational pattern of the macrocosm as understood in Kabbalah. And it should be stressed that this pattern is not some peripheral concern; it constitutes the core narrative in the *Zohar* and other key kabbalistic works. It is but a small stretch of the imagination, I think, to see this pattern recapitulated in the brain systems for consciousness mentioned above in terms of recurrent processing. A sensory stimulus triggers activity in lower neural centers, which "awakens" activity in higher centers, through which the "lamp" that brings the "blessing" of consciousness is kindled. The language of neuroscience and Kabbalah is clearly divergent, but the essential pattern being described is identical.

As I stressed at the beginning of this section, the parallel between the neuroscience of consciousness and this kabbalistic narrative of

macrocosmic principles leaves out the lifeblood of the latter, namely, its concern with transformation. The mystic is enjoined to arouse the “impulse above” in order to transform themselves and the Godhead. Such spiritual work is intended to bring harmony to the realm of the *sefirot* and to manifest the divine presence in the world. Kabbalah is replete with specific practices directed to achieving these aims. Given their transformative goals, the appropriate domain for evaluating these practices is psychology and especially those subdivisions – depth, and transpersonal, psychology – that explore the mind’s involvement in spiritual and mystical states.

The Psychology of Kabbalistic Transformative Practices

Begin to combine a few letters with many. Reverse them and revolve them rapidly, until your heart is warmed through the revolutions. Pay attention to their movements and to what you bring into being through their revolutions. And when you feel that your heart has been greatly warmed through the combinations and when you have derived understanding from them – new ideas that were never disclosed through human tradition and that you could not have known through intellectual analysis – then you are prepared to receive the divine influx. . . .

The above is from the thirteenth-century Abulafia. The “divine influx” to which he refers is evident not only in intellectual stimulation but also very much in embodied ways: The body may tremble, the heart is activated, and there is the feeling as if being anointed with oil. Such effects are frequently encountered in the study of mysticism and have been explained psychophysiology in terms of activation of the right temporal lobe of the brain cortex and *ergotropic* arousal of the sympathetic nervous system. However, the specific techniques that Abulafia teaches for achieving a higher state of consciousness are distinctively kabbalistic inasmuch as they draw on the mysticism of the Hebrew language and are intellectually complex.

A key source for all Hebrew language mysticism is the *Sefer Yetsirah* (Gruenwald 1971), thought to have been composed around the

fourth-century CE. The *Sefer Yetsirah* elaborates the Jewish tradition that God created the world using the Hebrew letters as His agents. The practices detailed by Abulafia entail emulating the divine work of creation described in the *Sefer Yetsirah*:

22 foundation letters [of the Hebrew alphabet]: He [God] engraved them, carved them, weighed them, permuted them, combined them, and formed with them all that was formed and all that would be formed in the future. . . . He engraved them with voice, carved them with breath, placed them in the mouth in five places. . . . He placed them in a wheel, like a wall with 231 gates. The wheel revolves forwards and backwards. . . . How? He weighed them and permuted them: *Alef* with them all and all of them with *Alef*; *Bet* with them all and all of them with *Bet*. They continue in cycles and exist in 231 gates. Thus, all that is formed and all that is spoken derive from one Name. (*Sefer Yetsirah* 2:2-5)

For the *Sefer Yetsirah*, then, all things come into being through permutations of core elements, the “231 gates” being the number of two-letter combinations achievable from the complete set of 22 letters in the Hebrew alphabet. Stripped of its theological connotations, the logic enunciated here is commensurate with that operating within the biological sphere; permutations of the DNA code give rise to all the formations of life.

Those following traditions relating to the teachings of Abulafia and others emulate all the processes described in the above extract inwardly, that is, in a concentrative state of consciousness using techniques of visualization, breath control, chanting, etc. Thus, for example, “revolving” the letters entails bringing together pairs of letters, perhaps in the mind’s eye, or in writing, or through chanting with a range of associated vowels.

Research has shown that practices fostering *mindfulness* increase levels of well-being and help combat a range of psychological and physical conditions. Although there have been no studies examining the psychological effects of these specific kabbalistic practices, the concentrative state they foster bears similarities to states associated with Buddhist mindfulness practices. However, any serious evaluation of the kabbalistic practices must acknowledge their most

distinctive feature, namely, the central role of language in the various techniques used. As Idel has noted, these kabbalistic practices are directed to *deconstructing* language as a semantic system. Given the role of language in structuring our sense of self and the world of experience, the practices are likely to bring about a lowering of ego-awareness and changes in our relationship to reality (Lancaster 2005). To use one of Abulafia's analogies, the "knots" which bind us to our world become untied and are reconnected to the divine.

For the eighteenth-century kabbalist and Hasidic master, Dov Baer, the Maggid of Mezeritch, "transformation comes about only by passing through nothingness." In the wake of Freud, the involvement of the unconscious in psychotherapeutic change is well established. Many psychotherapeutic schools recognize that nulling the mind from ego-based thought is essential in order to encounter the more transformational unconscious content. Indeed, the Maggid developed a concept of the unconscious, understood as the link between the divine and the human mind. Late in his life, Jung acknowledged that the Maggid's scheme was a forerunner of his own approach to the transpersonal unconscious.

While the specific Hebrew term the Maggid uses denoting the unconscious dates only from the eighteenth century, early kabbalistic material is fascinated by the concealing and revealing of thought, as we saw above. God's thought that engenders creation develops from an initially concealed state through to being revealed and finally re-concealed within the outer manifest world. From the human perspective, tracing thought to the concealed place of its source brings the longed-for encounter with the *Shekhinah*, the feminine presence of God.

The various themes I have touched upon come together here, for psychology connects with physics in conceptualizing the "concealed" unconscious realm as being the multipotential ground from which the particulate conscious domain arises. The logic of time and space are evidently unknown to the psychoanalytic unconscious, just as they have no reality in Bohm's

implicate order. And from its more empirical research base, cognitive neuroscience has demonstrated that unconscious brain processing entails multiple parallel instantiations of possible meanings; the unconscious is characterized by holistic operations. Kabbalah, physics, neuroscience, and psychology seem to meet in their respective formulations of the known and the unknown.

The *Alef* resembles the brain. Just as, in the case of the letter *Alef*, when you bring it to mind you open your mouth, so with thought – when you think a thought to the infinite and boundless....
(The *Bahir*.)

The Tradition for Dialogue Between Science and Religion

Science and religion represent very complex entities. Diversity reigns on both sides. The relationship between science and religion has gone from unity over conflict and condemnation to separation. The state of separation is in many ways a natural reaction to the confrontation between religion and natural science that grew out of the controversy following Darwin in the

late nineteenth century. After that confrontation, the unity among the sciences was lost forever. The theological reconstruction that was necessary in order to adapt to the new situation lasted nearly a 100 years. By then, the now classical neoorthodox position had been formed: Religion and science are separate and mutually exclusive realms of human thought.

Dialogue between science and religion is an attempt to overcome this separation. The situation of separation developed so strongly because such different schools and isms as scientism, positivism, and existentialism could agree that theology and natural science belong in two different fields. The position is further strengthened by linguistic arguments (Wittgenstein's theory of language games). Defining religion as an independent autonomous language game means that religion is seen as a way of life that does not need to justify its concepts. This immunity to falsification – sometimes labeled “Wittgensteinian fideism” – threatens to isolate the religious language game from other intellectual disciplines and religious communities. An appealing way out of the dichotomy is to seek in the everyday language the common language out of which all the language games have grown insisting that there are not two languages, a language of religion and of science, but one language, ordinary discourse modified in different ways. Another way out of the dichotomy is to maintain a common meeting place that would then be a kind of metaphysics (Whitehead; K.E. Løgstrup).

Is This Science? Is This Religion?

The natural sciences can give us valid knowledge of reality. But because it is reductionist in its approach to reality, it threatens to end in an abstract spirituality in which nature is reduced to a case of general laws and an area for using technology. Other approaches as phenomenological analysis, metaphysical speculations, and religious interpretations must be maintained in order to give the full picture. Somebody have – following Niels Bohr – used the notion of

complementarity to validate different approaches to reality that each from their perspective can contribute to the common understanding. If they exclude each other, the state of separation is cemented. But reality cannot be divided into distinct areas either scientifically and technically controlled or religiously interpreted. Reality is one. This one reality can be seen in different perspectives, but the underlying unity needs to manifest itself in the way we talk about it.

Relevance for the Field Science and Religion

Dialogue is a conversation which proceeds from a commitment to one’s own stand point and a genuine openness toward the other. Dialogue means willingness to listen. The dialogical approach recognizes that there are shared areas of interest between science and religion and that each have their own distinct perspectives. Following dialogue, a fuller integration and interaction between the different perspectives will continue to develop. In a model of reciprocal interaction within the field of science and religion, the various approaches, languages, attitudes, and objects of both theology and natural science are brought into relationship with each other. The disciplines keep their integrity and follow their own inner logic, but in order to gain a fuller picture, they need to interact. This model

of reciprocal interaction can help as an orientation in a world where the religious encounter has become globalized.

The Models for Interreligious Dialogue

Interreligious dialogue involves a desire to understand those of another faith better and learn from one another, leading to an ongoing reflection of one’s own faith and practice. As it promotes mutual knowledge, the same model can be used in both forms of dialogue, the interreligious and the one between science and religion.

In the field of interreligious dialogue four different forms of dialogue have been identified:

- In the *dialogue of life*, believers of different religions encounter one another in the ordinary course of life. In order for the community to thrive, it is vital that one relates to the other with respect and attention, recognizing the basic community that incorporates all people in spite of differences.
- The *dialogue of intellectual exchange* is often an area for experts. Faith seeks understanding, and theologians and religious scholars grapple many times with issues that cut across religious lines. Through an exchange on the intellectual level, it is possible to get a deeper understanding of the different faith traditions.
- In the *dialogue of spiritual experience*, an attempt is made to share in one another’s

search for the experience of God. In such a dialogue, spiritual resources can be shared enriching the religious experience.

- The *dialogue of common action* can take place at different levels. Common human and spiritual values can be promoted; alliances can be formed in order to transform the human community.

Dialogue between people of different faiths is necessary not only for instrumental reasons. Because the deepest motivation for dialogue is the common search for truth, science has a role to play, because science is also relentlessly seeking truth. It might not be the all encompassing truth, but what is established as scientific truth not only needs to be taken into account but it must also be respected in a dialogue between different faiths. But as it is always preliminary, it needs to be complemented with the insights gained in the world's philosophical and religious traditions.

What Are the Ethical Principles and Key Values?

The dynamic interaction between different religious traditions and the sciences must be carried out in an atmosphere of mutual respect and recognition of the fact that both the sciences and the religions are pursuing their endeavors in order to obtain truth. Scientific truth must be complemented with the insights of wisdom from the age old religious traditions. The proof of the truth claims within science and religion is of a different kind, but it should also be recognized that there are ways of knowing embedded in religious traditions of wisdom. Religions order and create structure in human lives; they give meaning, foster community, and provide liberation. Interreligious dialogue is furthered by a frank and truthful exchange on how the different traditions can contribute to order and community, meaning and liberation. Sustained by faith, nurtured by hope, and carried by the love of God, all people are called to engage in dialogue and to interact in a peaceful and truthful way with the fellow human being and the whole of creation.

Science is a social institution. Scientific work takes place in universities, academies, research institutes, and companies. It is funded by

governments, foundations, and corporations, all of which have institutional goals and interests. It is embedded in societies, with particular forms of solidarity, conflict, and inequality. For example, who is able to become a scientist depends on the broader education system which may tend to be meritocratic or may exclude on the basis of class, race, and gender. Just as sociologists study political institutions and education systems, sociologists of science study the institutional workings and social practices of science. So far, so straightforward and uncontroversial. But social life also centrally involves what people collectively believe and how beliefs are ordered and treated as true or false. The knowledge that scientific institutions produce filters through everyday life, and is employed and also contested in public. How scientific knowledge moves through society, informs political debate, and becomes subject to public controversy are therefore key concerns for the sociological study of modern societies. But does sociological explanation extend to the content of scientific knowledge itself? Is scientific knowledge social in the sense of beings shaped by social relations, values, and interests?

Contemporary sociologists of science argue that as scientific knowledge is produced in social institutions by human beings in definite social relations, its content is shaped by this context. What counts as science, what is denied scientific status, how scientific controversies are engaged and resolved, how local laboratory practices are transformed into more widely recognized truths are collective activities and accomplishments that call for sociological explanation. But the claim that the content of scientific knowledge is social has been probably the most controversial of all sociological ideas. It has been seen to threaten the special status claimed by science as the institutional embodiment of public truth and reason. In the so-called Science Wars of the 1990s, sociologists were accused of denigrating and undermining science and opening the door to a new irrationalism in which New Age mysticism and Creationism would thrive (Labinger and Collins 2001).

The sociology of scientific knowledge has its origins in the work of Karl Marx, Karl

Mannheim, and Robert K. Merton, but goes beyond these forerunners by developing a systematic sociological analysis of the epistemic content of science. Marx's dictum that "The ideas of the ruling class are in every epoch the ruling ideas" suggested that social relations of class determined what societies took to be knowledge (Marx and Engels 1972). However, Marxists have disagreed about whether this social determination of knowledge applies only to ideology, understood as false belief, or whether it is the case also for science. Orthodox Marxists tended to reserve special epistemic status for science and to treat Marxism as the highest form of science. The sociologist Karl Mannheim sought to extend the analysis of social determination beyond the critique of ideology-as-falsehood through the notion of "total ideology" put forward in his 1936 work, *Ideology and Utopia* (Mannheim 1936). Ideology, for Mannheim, formed a total worldview that was not necessarily a mere illusion. But Mannheim still held back from applying his analysis of the social determination of knowledge to science.

The mid-twentieth century American sociologist Robert Merton wrote extensively about the sociology of science. He deliberately eschewed the sociology of knowledge, insisting that the central question for sociology of science should be the "ethos" or "normative structure" of science. Merton wrote in 1942 that science was demarcated from other social institutions by its values of universalism, disinterestedness, organized skepticism, and communism (which he later renamed "communalism") (Merton 1973). These values were appropriate for the production of universal truth. In contrast with what he called the "acid quality" of the sociology of knowledge which tended to "indict, secularize, ironize, satirize, alienate, devalue," Merton's was a sociological celebration and defense of science (Merton). Sociologists of science in the Mertonian tradition studied the social conditions that would tend to promote or impede science.

However, the publication in 1962 of Thomas Kuhn's groundbreaking historical and philosophical study, *The Structure of Scientific Revolutions*, made the Mertonian demarcation of

sociology of science from the sociology of knowledge increasingly untenable (Kuhn 1970). Kuhn's rethinking of the history of science suggested the deep social commitment of scientists to a paradigm, their resistance to abandoning fundamental theoretical assumptions, and the ways in which scientific revolutions opened the boundaries of science to broader social influences beyond those of the discipline. According to Kuhn's model, scientific change could not be treated as linear and exclusively rational. For a new generation of sociologists of science in the 1970s, Kuhn's analysis opened the way for a sociology of the epistemic content of science. At the Science Studies Unit at Edinburgh University, David Bloor and Barry Barnes put forward the "strong programme in the sociology of knowledge" which insisted on the "symmetry principle" of giving the same type of explanation for true and false belief (Bloor [1976] 1991; Barnes and Bloor 1982). The sociology of knowledge would extend to science. It followed from symmetry that the sociologist should adopt a relativist attitude toward the knowledge-claims being studied, bracketing the question of truth or falsity in order to focus on the social process by which scientific findings and claims come to be socially established as "true" or "false."

A key focus of early empirical and historical work in the "strong programme" was the influence of social interests on science. For example, Steven Shapin analyzed the way in which changing class relations affected the reception of phrenology in nineteenth-century Edinburgh (Shapin 1979). In their pioneering work on the rise of experimental science in early modern England, *Leviathan and the Air Pump*, Shapin and Simon Schaffer argued that "Solutions to the problem of knowledge are solutions to the problem of social order" (Shapin and Schaffer 1985). Later work by Shapin, examining the experimental program of Robert Boyle and the Royal Society, has emphasized the dependence of scientific knowledge on relations of trust (Shapin 1994).

At the University of Bath, Harry Collins developed the "empirical programme of relativism," analyzing the social dynamics of scientific

controversies. Through participant observation of scientific work, Collins developed the concept of "tacit knowledge" coined by the chemist and philosopher Michael Polanyi (Polanyi 1964). Collins' studies show that scientific knowledge consists not only of explicit knowledge of the sort found in journal articles, but in skills and assumptions that are often embodied and implicit in practice. Tracing how tacit knowledge is shared and communicated involves illuminating the social networks of scientific communities or core-sets and the informal modes of scientific collaboration and communication. Collins also developed the key concept of the "experimenter's regress," showing the inherent problems in replicating experiments and thereby casting doubt on rationalist explanations for how scientific controversies come to be resolved (Collins 2004). A key focus for sociologists and anthropologists of science has been the thick description of laboratory practices and the mundane forms of reasoning employed in laboratory work (Latour and Woolgar 1979; Knorr-Cetina 1981; Lynch 1985; Traweek 1988; Pickering 1995).

Bruno Latour's actor-network theory challenged the primacy that the "strong programme" accorded to social explanation. Actor-network theorists provide what they regard as fully "symmetrical" accounts of scientific activity by treating nonhuman biological and physical entities as "agents" assisting or frustrating human goals (Latour 1993). Michel Callon's study of an attempted solution to the problem of the decline in the scallop population in St. Brieuc Bay exemplified actor-network theory by showing how the solution depended on a complex set of relations between the scientific researchers, the fishermen, and the scallops themselves (Callon 1986).

Feminist research has illuminated both the gendering of scientific knowledge, including the role of gender imagery in the scientific and technological domination of nature, and the way in which assumptions about gender difference are constructed and maintained through science (Harding 1986; Merchant 1980; Martin 1991).

Public controversies about science and technology, and the commercialization of science,

have made questions of governance and regulation a focus of attention for sociologists of science. Sheila Jasanoff's book, *Designs on Nature*, examines the politics and regulation of the life sciences in Britain, Germany, and the United States. The book pays particular attention to the contrasting "civic epistemologies" of these countries and argues that political institutions and political cultures are "coproduced" with science (Jasanoff 2005). Increasingly science is coproduced with capital and industry, and Daniel Lee Kleinman's book, *Impure Cultures*, demonstrates the depth to which these commercial relationships affect the practice of university biology (Kleinman 2003).

"Science Wars" accusations that sociologists were engaged in the denigration of science were based largely on casual misreadings and misunderstandings of sociological work. But viewing science as social relations can involve critique of those relations (e.g., science's military-industrial connections) and it implies that scientists should be more reflexive about the ways in which their knowledge is embedded within social relations of power and trust. Public controversies over such issues as radiation risk, BSE, genetic modification, and vaccination risks show the failure of a technocratic model of one-way communication from scientists to the public. Brian Wynne's study of the relations between nuclear experts and Cumbrian sheep-farmers in the wake of the Chernobyl disaster has been an important spur for generating a more nuanced understanding of relations between scientific expertise and other forms of knowledge and cultural values in the broader society (Wynne 1996). Sociologists of science have been involved in rethinking scientific communication as a dialogue between scientists and the public and in developing new forms of public engagement with science (Wilsdon et al. 2005).

Science in Buddhism

Jason Slone

Tiffin University, Tiffin, OH, USA

Description

Buddhism is an Asian religion that is based on teachings attributed to Siddhartha Gautama, an upper-class male born in northeastern India in the fifth or sixth century BCE. Gautama became the “Buddha” (“awakened one”), according to tradition, upon achieving “enlightenment” as a result of engaging in a series of spiritual practices, most notably ► [meditation](#). After achieving

enlightenment, the Buddha is said to have gained a perfect understanding of the nature of the world and of human existence, and he spent the remainder of his life traveling and teaching as an itinerant mendicant. The religion of Buddhism is based largely on the teachings attributed to Gautama-Buddha.

Many authors and practitioners of Buddhism claim that not only are Buddhism and science compatible, but that Buddhism is inherently scientific. Buddhism is said to be scientific in at least four ways. First, unlike most other major world religions, Buddhism dismisses either the existence or the efficacy of supernatural deities. In this sense, some say Buddhism is atheistic. Second, Buddhism is said not to rely on blind faith, appeal to authority, or metaphysical speculation, for justification. Third, the Buddha’s understanding of reality is said to be in line with much of modern physics. Specifically, our experience of reality is illusory because though we see the world as having a stable and permanent existence, the world is actually a collection of parts that are constantly in motion as is held by the atomistic theory in ► [particle physics](#). Fourth, the Buddha’s understanding of human psychology, in particular the cause and alleviation of mental suffering, is in line with certain tenets of modern psychology, notably cognitive therapy (CT). According to Buddhism, human suffering is the result of improper thinking. Specifically, to be happy, Buddhism claims that a person must eliminate incorrect and dysfunctional thinking and replace such thinking with new habits of thought, which is achieved through the practice of meditation. Meditation is said to “tame the mind” and thereby “calm the soul.”

Inspired by anecdotal claims of meditation’s therapeutic benefits made by prominent scientists who practice meditation, a number of contemporary psychologists and medical doctors have experimentally tested this claim and obtained confirming results. This area of investigation, between meditation and neuroscience, is arguably the most active in all of Buddhism and science.

It should be noted that some scholars have recently called into question the degree to which

the Buddhism being presented as in line with modern science is in line with *Buddhism*. That is, scholars have questioned the historical authenticity of the type of Buddhism that is said to be scientific. The hypothesis is that the “scientific Buddhism” that is being presented as in line with modern science is actually a historical invention by Asian monks in the nineteenth century as a strategy of combating European colonialist claims that Asians and their religions were “backward” and in need of being “civilized” by Christianity and Europe. Regardless of its historical authenticity, though, even these scholars recognize that while constructed, this reformed version of Buddhism is now quite popular, both in the West and increasingly in Asia, and so is likely here to stay.

Self-identification

Science

Both supporters and critics of the notion that Buddhism is scientific acknowledge that “scientific Buddhism” was championed in the nineteenth century first by Asian Buddhists themselves, such as the Sinhalese ► [Theravada](#) Buddhist, Anagarika Dharmapala, but later championed by Western converts such as the American Henry Steel Olcott and the German-American, Paul Carus. Recently, prominent Buddhist leaders such as the fourteenth Dalai Lama, Tenzin Gyatso, and Chogyam Trungpa have advanced the notion that Buddhism is inherently in line with modern science. Similarly, Western scientists who practice Buddhism contribute to the self-identification of Buddhism as scientific. For instance, prominent scientists who practice or champion Buddhist meditation include psychologists Daniel Goleman and Richard Davidson, the medical doctor Daniel Siegel, the neurobiologist Francisco Valera, and the physicist Arthur Zajonc.

Religion

This is a difficult question, as the answer turns precisely on what constitutes a “religion” at all. Further, in many ways the scientific nature of

Buddhism is defined vis-à-vis traditional religion. Thus while classical Buddhism is infused with elements of traditional religion, such as ritual, devotion, and supernatural beliefs, those who view Buddhism as scientific often dismiss such practices as folk belief rather than Buddhism proper. However, there is no disputing the fact that worldwide, Buddhism as practiced by most Buddhists contains elements of traditional religion.

Characteristics

Arguably, the most unusual feature of Buddhism, in relative contrast to other major world religions, is the claim that Buddhism is an atheistic religion. However, this claim itself has been disputed as being based on a misreading of a widespread quote attributed to the Buddha: “No one saves us but ourselves. No one can and no one may. We ourselves must walk the path.” This quote can be interpreted to mean that no deities exist. Or, it can be interpreted to mean that though deities exist, they cannot provide salvation. If one assumes the former, Buddhism might be atheistic. However, if one assumes the latter, Buddhism is theistic.

Relevance to Science and Religion

Not only are many practitioners of scientific Buddhism interested in science and religion, they often see themselves as uniquely positioned – due to the features of Buddhism noted above – to be leaders of the science and religion dialogue. Buddhists regularly volunteer to be subjects in medical and scientific experiments, and an institution, The Mind and Life Institute, has been created specifically to further the dialogue between Buddhism and science.

Sources of Authority

As with all institutionalized religions, authority in Buddhism is occasionally contested. For

instance, members of the two major sects of Buddhism – Theravada and ► [Mahayana](#) – disagree over scriptural authority, monastic lineage, and so forth. Nonetheless, the most prominent figure in Buddhism and Science today, Tenzin Gyatso, is the theocratic head of the Tibetan government-in-exile in Dharamsala, India, and widely believed among Tibetans to be the fourteenth reincarnation of the Dalai Lama.

Further, scientists who champion Buddhism, such as Richard Davidson, Daniel Goleman, Daniel Siegel, Francisco Valera, and Arthur Zajonc, are seen as authoritative because of their scientific credentials and prominent research.

Ethical Principles

The ethical principles that guide Buddhism differ between monks and nuns, and the laity. Lay Buddhists are expected to follow five principles: no killing, stealing, lying, sexual misconduct, or intoxicants. However, monks and nuns are expected to follow a much larger set of ethical rules (227 for males, 311 for females) as outlined in a text known as the *Vinaya Pitaka*.

Scientists who conduct research on Buddhism are bound by the same ethical requirements all scientific researchers are expected to follow, such as not to distort the research process or fabricate data, and the ethical treatment of human subjects as outlined by the Institutional Review Board (IRB).

Key Values

The values of the Buddhism and Science movement can be said to be pragmatic empiricism whereby one should, to quote the motto of the Royal Society, “Take no-one’s word for it.” This claim is based on an oft quoted passage from a text known as the *Kalama Sutra – Anguttara Nikaya 3.65* in which the Buddha instructed:

Do not go by revelation.

Do not go by tradition.

Do not go by hearsay.

Do not go on the authority of sacred texts.

Do not go on the grounds of pure logic.

Do not go by a view that seems rational.

Do not go by reflecting on mere appearances.

Do not go along with a considered view because you agree with it.

Do not go along on the grounds that the person is competent.

Do not go along because [thinking] “the recluse is our teacher.”

Conceptualization

Nature/World

Nature and the world consist of smaller (unseen to the naked eye) parts that are in constant motion. Therefore, according to Buddhism, life is empty of any stable, permanent reality.

Human Being

Like the world around us, humans consist of smaller (unseen to the naked eye) parts that are in constant motion. Therefore, according to Buddhism, humans are empty of any stable, permanent reality such as a soul.

Life and Death

According to Buddhism, an individual’s life is the result of the transmigration of material from a previous life. At death, the material that constituted our bodies transmigrates into a new form, and that process continues on until one achieves parinirvana (via Buddhist practice). In Buddhism, parinirvana is the final stage which occurs upon the death of the body of someone who has attained complete enlightenment. It implies a release from the cycle of birth, life, death, and rebirth.

Reality

According to Buddhism, reality is not as it seems. We see reality as having a stable, permanent existence, but in fact it is constantly in flux and changing.

Knowledge

According to Buddhism and science, true knowledge comes from testing claims empirically.

Truth

According to Buddhism and science, truth can only be established through rigorous empirical testing.

Perception

According to Buddhism and science, our eyes can deceive us and therefore it is critical to test claims empirically and repeatedly to establish truth.

Time

In science, time is part of the measuring system used to sequence events, to compare the durations of events and the intervals between them, and to quantify the motions of objects. Scientists consider time to be linear in nature. In Buddhism, time is merely a feature of the mind.

Consciousness

According to Buddhism and contemporary neuroscience, consciousness is a continual series of individual moments or events. In neuroscience, however, many consider consciousness to be a product of brain function, and so “the mind is what the brain does.”

Rationality/Reason

According to Buddhism, suffering is caused by irrational thinking and that training the mind (via meditation) to be perfectly rational – and thus achieving Buddha-hood is the anecdote. However, in modern psychology there is great debate over the extent to which it is possible to train the mind perfectly. Some psychologists argue that the brain is a collection of modules that was designed by evolution to function rationally in a world that is much different from the one in which we now live. As such, we have, at best, bounded rationality, based on a mismatch between what brains are designed to do and what we need them to do in today’s environment.

Mystery

Some philosophers and scientists working in cosmology have argued that while we have solved two of the three great mysteries of life, namely why humans exist (answer: evolution) and how consciousness can exist (answer: brains), the last

will never be answered: why something exists rather than nothing. There are only two possibilities, it has been argued, and each is incomprehensible: Either the world was created (but by whom or what, and who or what created the creator?) or it has always existed (but where did it come from?). Likewise, the Buddha purportedly noted that human beings cannot know the answers to all of life’s mysteries and to try to do so is not only wasteful, it is counterproductive. Instead, we should focus our mental energies on problems we can solve, like alleviating mental suffering.

Relevant Themes

It is critical to note that Buddhist meditation is increasingly being recognized in the medical and scientific communities as having real therapeutic benefits. As such, it is safe to say that more and more scientific individuals may be looking to Buddhism as their religion of choice.

Science in Islam, Classification

Godefroid de Callataÿ
Institut Orientaliste, Université Catholique de
Louvain, Louvain-la-Neuve, Belgium

Related Terms

[Encyclopaedism](#); [Organization of science](#)

Description

The classification of science in Islam is a subject which needs to be investigated in reference to the historical and intellectual context of early Islam (Endress 2006). For about 150 years, the field of theoretic knowledge remained largely the prerogative of traditional sciences, like jurisprudence or theology, which could be viewed as grounded in the Qur'an and the traditions of the Prophet. From about 750 A. D., as a result of a large-scale movement of translation, philosophy and the rest of rational sciences (mathematics, physics, metaphysics, and logic, with their own subdivisions) as already cultivated in antiquity by the Greeks were incorporated too (de Callataÿ 2008a). One way or another, nearly all classifications in premodern Islam reflect this bipolarity between traditional (or “religious” or “Islamic”) sciences and rational

(or “philosophical” or “foreign”) sciences (Bakar 1998; Biesterfeldt 2000, 2002; Pellat et al. 1990; Vesel 2008).

Self-Identification

Science

In the same way as the page of contents in a book is part and parcel of this book, the classification of science in medieval Islam could easily self-identify as a science of its own, being a sort of natural corollary to the encyclopedic approach of reality. A typical example is the work known as the *Epistles of the Brethren of Purity*, a vast tenth-century encyclopedia of sciences consisting of about 50 epistles, one of which specifically concerned with one such classification of human knowledge (de Callataÿ 2008b).

Characteristics

What makes the classification of science distinctive among other disciplines in Islam is both its systematical and all-encompassing approach of reality.

Relevance to Science and Religion

For philosophers and humanists of medieval Islam, the organization of human knowledge served to stress the harmony between, and eventual reconciliation of, both traditional and rational sciences. In the eyes of people less favorable to the incorporation of foreign material into the building of Islamic thinking, the classification of sciences was a way to emphasize the superiority of traditional sciences over rational sciences, of revelation over human speculation, and, ultimately, of religion over science (in the modern sense of the word).

Sources of Authority

The sources of authority for the classification of science in Islam are the authors of classifications themselves, first and foremost the Greek masters,

most notably Aristotle, and then their Muslim epigones, such as Kindī, Fārābī, Ibn Sīna (Avicenna), or Ibn Khaldūn. What makes these sources authoritative is the intrinsic coherency of the classifications, along with the prestige and fame of the authors.

Ethical Principles

Some classifications of science, especially those meant to represent the traditional view, reflect ethical concerns. This is evidenced, for instance, from their rejection of a certain number of scientific arts or practices (such as alchemy, astrology, or logic) deemed to be incompatible with the “orthodox” view and therefore blameworthy.

Key Values

Coherency, comprehensiveness, and sense of hierarchy.

Conceptualization

Nature/World

God’s creation.

Human Being

An animal possessing a spiritual soul.

Life and Death

A characteristic affecting those beings in the world which are subject to decay. Biology or zoology did not exist as such in medieval classifications of science, although the distinction between the mineral, vegetal, and animal kingdoms was usually reflected by them.

Reality

What exists per se, as opposed to what has been devised. In Islamic classifications, rational sciences are sometimes called “real,” in opposition with the traditional sciences, which are assumed to have been conventionally “set up” for a certain purpose.

Knowledge

Theoretical and practical understanding of a subject.

Truth

Agreement with reality.

Perception

One of the faculties by which a human being, through the use of his senses, is able to understand the reality around him.

Rationality/Reason

Man’s ability to understand a subject by his own effort.

Science in Islam, Transmission

Godefroid de Callatāy

Institut Orientaliste, Université Catholique de Louvain, Louvain-la-Neuve, Belgium

Description

The transmission of science in Islam is a subject which needs to be investigated in reference to the historical and intellectual context of early Islam. Traditional sciences, that is, those sciences which could be viewed as grounded in the Qur'an and the traditions of the Prophet, used to be transmitted by generations of experts from the very beginning of Islam (Kraemer 1986; Makdisi 1981; Rosenthal 1975; Van Ess 1991–1997). Philosophy and the rest of the rational sciences were incorporated at a later stage (from about 750 AD, roughly coinciding with the accession to power of the 'Abbasids and the foundation of Baghdad), as a result of an unprecedented movement of translation into Arabic of ancient traditions (mainly Greek, but also Persian, Indian, and many others as well) that had survived in various communities of the Near East (Endress 2006; Saliba 2007;

Wasserstein 1989). This formidable undertaking, made possible by a wide range of favorable factors (economic, social, political, cultural, etc.) acting at the same time, would not be over before the end of the tenth century when, with the exception of a limited amount of specific literature not deemed of interest by the scholars of Islam (most notably ancient Greek belles-lettres and history, and Christian literature in general), nearly all Greek sources accessible in that part of the world seem effectively to have been made available in the Arabic language (Gutas 1998). The field ranges from logic and metaphysics to ethics and politics, from medicine and the natural sciences to the sciences of the number (arithmetic, geometry, astronomy, and music) and the technical sciences. The other impressive feature is the unusually rich melting pot of cultures, races, and religions in which diverse groups of translators, copyists, and scientists were able to work with one another for more than two centuries, and this obviously in the absence of a centralized program or sponsorship, although some caliphs became quite famous for their support. Among scientists, Christians were in the majority, but there were also Jews, Persians, Arabs, and even idolaters. This multiculturalism was also to favor significantly the incorporation of sources that did not ultimately derive from Greece, but rather from India, Iran, and Ancient Mesopotamia. The succeeding decentralization of power in Islam may be viewed as having played a positive role in the development and transmission of the sciences as well, since it widely contributed to the availability of patronage, as newly arrived rulers competed with each other to take the place of the 'Abbasid caliphs as protectors of the arts and the sciences.

Self-identification

Science

The transmission of science in Islam is a cultural and intellectual phenomenon. It cannot self-identify as a science, since it was never meant to follow or obey predefined rules.

Sources of Authority

The sources of authority for the transmission of science in Islam are the authors themselves. The *Fihrist*, a monumental catalogue of the books available in Arabic (whether the result of a translation or not) compiled on every branch of knowledge by the tenth-century Baghdad librarian Ibn al-Nadīm lists about 4,000 authors, ancient or modern.

Description

Some people seem to think that there are no real limits to the competence of science, no limits to

what can be achieved in the name of science. There is no area of human life to which science cannot successfully be applied. A scientific account of anything and everything constitutes the full story of the universe and its inhabitants. Or, if there are limits to the scientific enterprise, the idea is that, at least, science sets the boundaries for what we human beings can ever know about reality. This is the view of *scientism*.

From a historical perspective, perhaps the most well-known proponent of scientism is the French social philosopher Auguste Comte, with his attempt to create a religion based on science – the “Religion of Humanity” 1852. Another interesting and far-reaching attempt to have science take over many of the functions of religion, and thus itself become a religion, was undertaken by the German chemist and Nobel prize-winner Wilhelm Ostwald (1912: 94–112). He argued for science as an “Ersatzreligion” – a substitute religion. Yet, many different forms of scientism have emerged over the last three centuries, and during the most recent decades, a number of distinguished natural scientists, for instance Peter Atkins, Richard Dawkins, Carl Sagan, and Edward O. Wilson (1978), as well as philosophers such as Daniel C. Dennett and Patricia Churchland have advocated scientism in one form or another (Atkins 1995: 132).

But what, more precisely, is scientism? Though it is not at all easy to define, we might say that someone is a proponent of scientism if he or she believes that everything (or at least as much as possible) could and should be understood in terms of science. Be aware here that the notion of science is used in the restricted way that is common in English usage, though not in the German or Swedish tradition. Thus, the term covers only the natural sciences and those areas of the social sciences that are highly similar in methodology to the natural sciences.

Another concept that could be invoked in this context is “scientific expansionism,” and this explains quite well what the project is all about. Namely this: the proponents believe that the boundaries of science (that is, of the natural sciences) can and should be expanded in such a way that what has not previously been understood as

amenable to scientific methodology can now be brought within the scope of science. Science can answer many more questions than we have previously thought possible.

In its most ambitious form, scientism can be defined as the view that science has no real boundaries; that is to say, eventually it will answer all empirical, theoretical, practical, moral, and existential questions. Science will in due time solve all genuine problems that humankind encounters. How, exactly, the boundaries of science should be expanded and what, more precisely, it is that is to be included within science are issues on which there is disagreement. Some proponents of scientism are more ambitious than others in their extension of the boundaries of science. That is to say, they are all scientific expansionists but in different ways and to different extents.

Perhaps the most well-known form of scientism, epistemic scientism, expresses a particular idea about the boundaries of knowledge, saying that the only genuine knowledge about reality is to be found through science and science alone. The only kind of knowledge we can have is scientific knowledge. Everything outside of science is taken as a matter of mere belief and subjective opinion. Consequently, the agenda is to strive to incorporate as many other areas of human life as possible within the sciences so that rational consideration and acquisition of knowledge can be made possible in these fields as well. If one holds this epistemological view, then it is of course not difficult to understand that one would believe that everything (or at least as much as possible) could and should be understood in terms of science – because what we cannot understand and explain in terms of science is something that we cannot know anything about at all. This is not the view that science is the paradigm example of knowledge or rationality, but the view that the only genuine knowledge about reality is to be found through science and science alone.

Epistemic scientism raises an obvious challenge to the religions of the world. For example, Christianity could only give us knowledge about God, human beings, and the world if those knowledge claims could be confirmed by

the methods of the natural sciences, because genuine knowledge – according to this version of scientism – could only be obtained by such methods.

Scientism has been criticized by many scholars who have taken part of the science-religion dialogue, such as Ian Barbour, John Haught, Mikael Stenmark (2001), and Keith Ward (1996) and in culture in general by people such as Bryan Appleyard, Mary Midgley (1992) and Huston Smith. Smith even think that “the greatest problem the human spirit faces in our time is having to live in the procrustean, scientific worldview that dominates our culture” (2001: 202). Depending on what form of scientism analyzed and what understanding of religion defended, the critical responses have looked differently. The main criticism, however, is that the advocates of scientism in their attempt to expand the boundaries of science rely in their argument not merely on scientific but also on philosophical premises and that scientism therefore is not science proper, but naturalism or atheism disguised.

Perhaps the most embarrassing problem for spokespersons for scientism is that one of its central claims seems to be self-refuting. The difficulty is that the scientific belief that we can only know what science can tell us (epistemic scientism) seems to be something that science cannot tell us. How can one set up a scientific experiment to demonstrate the truth of that claim? It seems not to be possible. But we cannot know that scientific knowledge is the only mode of knowledge unless we are able to determine this by scientific means. This is so, simply because science – according to epistemic scientism – sets the limits for what we can possibly know. Hence, the claim that we can only know what science can tell us falsifies itself. If it is true, then it is false.

Scientist-Practitioner

Kevin S. Masters

Department of Psychology, University of Colorado Denver, Denver, CO, USA

A model of training wherein practitioners in a given field (e.g., behavioral medicine, health psychology) are trained to apply the findings, processes, and principles of science and scientific investigations to their professional practice. These practitioners may also be involved in conducting scientific investigations of their own. Thus practitioners incorporate methods of treatment that have received scientific empirical support and they engage in decision making that utilizes the logic of hypothesis testing informed by research findings and clinical experience. The model was first proposed as a method for training clinical psychologists at the Boulder Conference on Graduate Education in Clinical Psychology (1949) held in Boulder, Colorado, USA, but has since been adopted by many professions involved in treating human conditions.

Second Law of Thermodynamics

Russell Stannard

Department of Physics and Astronomy,
Open University, Milton Keynes, UK

There are various ways of formulating this law of nature, but generally speaking, it holds that in a closed system, disorder increases with time. For example, it is much more likely that a chimney will collapse into a pile of rubble rather than the reverse: a pile of rubble spontaneously assembling itself to produce a chimney. The fact that sometimes a pile of bricks can be assembled to form a chimney does not violate this law. In this case the pile of bricks is not a closed system. Their assembly requires input from construction workers. When “the system” is extended to include the workers, together with their breakdown of food to produce energy, etc., then the second law is seen to hold.

Secular

Leonard Levin

Jewish Theological Seminary of America,
South Orange, New Jersey, USA

Profane, ordinary, the opposite and complement of “sacred.” At the risk of oversimplification, it may be suggested that in Western society the realms of the sacred or religious and the secular

have historically had three different relations: (1) hegemony of the religious outlook over the whole of society comprising both the sacred and secular realms (ancient and medieval periods); (2) competition of the religious and the secular for political and intellectual hegemony (late medieval and early modern); and (3) political and intellectual hegemony of the secular, along with privatization of the religious (late modern period). The application of this schema to the topic of “secularism and Judaism” has the following consequences:

- In Biblical society, the religious authority demarcated the realms of the sacred and the profane (see Ezekiel 44:23).
- In the Middle Ages, the religious philosopher adjudicated the claims of reason and revelation in a way that preserved hegemony of the religious outlook.
- Spinoza was typical of Enlightenment thinkers in challenging the veracity of Scripture and advocating the hegemony of the secular ruler.
- By calling a Jewish Sanhedrin in 1806, Napoleon asserted the hegemony of the secular state over religion; the nineteenth-century Jewish movements complied by adapting Jewish religion to the conditions of modern civil society.
- For a time, modern secular movements asserted modes of Jewish affirmation that dispensed with religion altogether; however, the commonest modes of Jewish affirmation take a religious form – though with the individual autonomy that is one of the hallmarks of modern secularity.

Description

The intersection of ► [secularism](#) and ► [Judaism](#) will be considered here under four headings:

1. The place of the ► [secular](#) in classical Jewish thought
2. The impact of secular thought on the modern versions of Jewish religion, especially during the period of modernization in the nineteenth century
3. Self-styled “secular movements” in modern Judaism (such as Zionism) that conceive of a kind of Judaism divorced from religion
4. The question of positive Jewish identity and Jewish content in the lives of Jews who affiliate neither with Jewish religion nor with secular Jewish movements

The Secular in Classical Jewish Thought

Biblical Jewish thought. If by “secular” we mean “worldly,” all religion has a secular element, for all religion must include the world somehow in its map of reality. The author of Genesis 1 conceived the world as the creation of God, but also as a good in its own right. The God of the Hebrew Bible situates humankind in the world for their

benefit. He promises fertility of crops, livestock, and human progeny if people would obey His will. The pleasures of life are affirmed as good, subject to their enjoyment within lawful limits and constraints. Although worldly pomp and splendor can lead to corruption and abuse, they are affirmed as legitimate under the proper circumstances. Political rulers may exercise power if they do so justly, while acknowledging God as the supreme ruler.

Like most ancient cultures, ancient Israel posited a formal distinction between those areas of life that were “sacred,” subject to the control and governance of the priesthood, and “profane,” free for use by the laity with a lesser degree of restrictive regulation. The “profane” realm of Biblical experience foreshadows the “secular” realm of medieval Christendom, which evolved into the modern secular world.

Peter Berger (1967) follows Max Weber in characterizing the created natural world of the Hebrew Bible as “disenchanted” in comparison with the god-filled plenum of nature in the pagan mythic conception. In that respect, the Biblical outlook is perhaps somewhat more “secular” than the outlook of the Enuma Elish, the Vedas or the Nibelungenlied. On the other hand, the Biblical authors did not arrive at a systematized vision of physical nature obedient to natural law, as Greek science did. The Biblical authors recognized the exceptionality of certain miracles (see especially Numbers 16:29–30), but generally viewed the world as following an overall orderly course that is, nevertheless, subject to divine guidance and providence. In this outlook, there is not a sharp dichotomy between “natural” and “supernatural” realms or modes of causality, as would appear in medieval conceptualization of “miracle.” There is no word in Biblical Hebrew for “nature,” “natural,” or “supernatural.” Though “Heaven” is preeminently the abode of God, it is also the source of meteorological phenomena; it is the visible sky, not an invisible transcendent realm. In all these respects, though the Biblical world-outlook includes “secular” elements, it is lacking in the sharp “sacred-secular” dichotomy that characterizes the modern debate.

Rabbinic Judaism. Rabbinic thought arose at least in part to defend the integrity of the Biblically based ethos from the challenge posed by the Greco-Roman classical culture – inclusive of religious paganism, art, and philosophy. For our purposes, the following developments are noteworthy:

- (a) Rabbinic Judaism defined a normative structure (halakha) governing a wide array of domains – divine worship, civil law, marital law, eating, the work-rest cycle, and relations between Jews and non-Jews in daily life. Comprising areas like civil law under halakha was simultaneously an affirmation of the legitimacy of secular pursuits and staking the claim of sacred law to govern it.
- (b) Rabbinic hermeneutics sought to ground all normative discourse (insofar as possible) in the exegesis of sacred Scripture. In doing so, it affirmed implicitly that sacred authority holds sway over all existence, and denied the legitimacy of any radically secular domain that was free of divine governance. It similarly accentuated the radical difference between “Israel” and “the [gentile] nations,” thus affirming the ultimate value of the Jewish people who live by God’s law, and denigrating the value of the pagans and “sectarians” (i.e., Christians and Gnostics) who do not.
- (c) On the other hand, rabbinic ethics affirms a category *derekh eretz* (literally “the way of the world”) which has many shades of meaning but is very close in some of its significances to the Stoic concept of “natural law.” As such, it affirmed the validity of a secular normative standard as both compatible with and complementary to its own religious normative standard.
- (d) Rabbinic cosmology accommodated to the prevailing natural law conceptions by trying to harmonize Biblical miracles with an overall affirmation of natural order – for instance, by saying that God provided for these miraculous phenomena in the liminal time-slot between the sixth day of creation and the first Sabbath.

Medieval Judaism. Medieval Jewish philosophy (in particular, that of Maimonides) sought on

the one hand to set up a sharp opposition between the rabbinic Jewish outlook, deriving all normative assertions from the Bible, and the secular philosophical outlook such as that of Aristotle. At the same time, it tried to mediate this opposition by achieving an accommodation, in which the Jewish and philosophical outlooks would be synthesized where possible (such as in proving the existence of God), and rendered distinct where synthesis was impossible (such as on the issue of the creation or eternity of the world). Maimonides’ accommodation with Aristotelianism had the following implications for our problem:

- (a) It affirmed the validity of secular reason as a legitimate intellectual method.
- (b) It enlisted secular reasoning in support of traditional beliefs, particularly with respect to proving the existence of God and articulating a purified conception of God’s nature.
- (c) It demanded the reinterpretation of Biblical assertions in order to render them compatible with philosophical reason, particularly with respect to anthropomorphism; this left the Bible authoritative as to “word” but reason authoritative as to “meaning.”
- (d) It reinterpreted the very notion of “revelation” (i.e., prophecy) in a sense almost synonymous with philosophical enlightenment, and (in *Guide* III, 40, following Alfarabi) Maimonides offered a portrayal of the ideal prophet-legislator in the mold of Plato’s philosopher-king.
- (e) It demanded a rationalizing and ethicizing interpretation of Jewish normative injunctions, particularly in Maimonides’ interpretation of certain areas of Jewish law in his code, the *Mishneh Torah*.
- (f) On the other hand, it used the logical consistency of philosophic reasoning to solidify the definition of the demands of the sacred realm, for instance, in Maimonides’ codification of the sacred law and in his defining for the first time a definite Jewish creed as a boundary-marker for demarcating Jewish legitimacy.

In short, the Maimonidean formulation of Judaism enlarged the area of the legitimate use of secular reason, both in itself and in the service

of sacred knowledge. At the same time, it sharpened the sacred-secular distinction in new ways, which would ultimately play a part in defining the battleground of secularization in the modern period.

The Impact of Secular Thought on Jewish Religious Modernity

Spinoza. Modern Jewish thought begins, in many important respects, with Spinoza. Harry Wolfson observed that Spinoza broke apart the synthesis of revelation and reason that had prevailed in medieval thought, primarily by discrediting (in his *Theological-Political Treatise*) the Bible's claim to embody infallible divine truth. Thus, secular reason for the first time posed a potentially mortal threat to the viability of traditional Jewish faith altogether. Moreover, Spinoza proposed, in his *Ethics*, a God-concept radically different from the personal, transcendent God of the Bible and medieval theism, and (some would say) dangerously close to the vanishing God of modern atheism. Nevertheless, Spinoza's position on both these issues developed organically and dialectically out of Maimonides' compromising synthesis. One might say that the substance of the challenge of secular philosophical reason to Biblically based Jewish faith was perceived similarly by Maimonides and Spinoza, only that in Maimonides' assessment the challenge could be met through compromise and reconciliation, whereas in Spinoza's assessment it could not, and the two outlooks would have to go in their separate ways.

Nevertheless, it has been the general direction of modern Jewish religious thought to try to rescue Jewish faith from Spinoza's challenges. This has meant establishing new syntheses of faith and reason that differ from Maimonides' synthesis by conceding the force of secular reason in stronger terms than Maimonides would have allowed. Specifically:

(a) Spinoza initiated secular scholarly analysis of the Bible as a literary and historical document. Modern Jewish theologians reconstruct the narrative of Jewish history, and the

Jewish historical theology that grows out of it, based on this new scholarly foundation, which is secular in its methodology.

(b) Spinoza radically redefined God to conform to the emergent modern scientific worldview. Modern Jewish theologians may disagree with the specifics of Spinoza's theology. But they are generally agreed that Jewish theology must adapt its assertions to agree with the findings of modern science (particularly evolution, after Darwin). And the radical immanence of Spinoza's pantheism finds a modified echo in the pantheistic tendencies of many contemporary Jewish theologians. The revaluation of divine immanence may be seen as "secularizing" inasmuch as it brings God more into interaction with the world than the medieval transcendent God.

Enlightenment and Emancipation. From the eighteenth century onward, Jews of Western Europe (and later Eastern Europe) tended increasingly to adopt the intellectual ideologies growing out of the European Enlightenment, in tandem with their attempt to become integrated politically, socially, and culturally in the nation-states of modern Europe. For these purposes, they adopted ideas that had a secularizing impact on general European thought, which tended also to advance the interests of Jewish integration (See Schweid 2008). By the same token, the same ideas, when applied internally within Judaism, had a destabilizing effect on the traditional Jewish outlook and required the formulation of new Jewish religious ideologies to achieve a new equilibrium under which Jewish religion could exist in the modern age. Among these ideas (see Berger 1967; Martin 1969):

- (a) All human beings are fundamentally equal, deserving equal rights and equal treatment under the civil law.
- (b) All human institutions (including religion) are to be evaluated according to the extent to which they further human happiness, conceived in universal, nondogmatic terms (though consistent with a Deist conception of a universal, benevolent God).
- (c) Among the universal human rights is liberty of conscience; hence, all persons should be

free to choose whatever religion suits them. Religious law (whether Christian law imposed on Jews, or rabbinic law imposed within traditional Jewish communities) should never be enforced; religious compliance is voluntary and a matter of private conscience.

- (d) All religious dogmas (including the very belief in God) are unprovable. Disputation among religions is fruitless. In a tolerant, ecumenical society, all religions conducing to the public good are to be tolerated. Religious adherents should forswear triumphalist pretensions and agree to disagree amicably in the interest of the public good.

The net effect of adopting these principles was to incorporate the secular tenets of individual freedom and utilitarian measurement of success into the fabric of the modern denominations of Judaism, to a varying extent across the Reform, Conservative, and Modern Orthodox movements. Traditional Judaism had sought to exercise hegemony over all areas of Jews' lives. Modern Judaism reduced its sights to fostering a voluntary compact among its members, to adopt those portions of the Jewish religious legacy that could be justified as in agreement with the norms of liberty and pursuit of happiness that prevailed in secular society.

More generally, Judaism followed the example established by Western religion generally during the period of early modernism. Whereas in the medieval world, religion had sought to govern the tenor of life in its totality – outlook, social values, and sacred occasions, as well as maintaining a hefty political presence – in the modern world, religion is relegated to a much narrower, specialized domain. It was modern religion's business to maintain personal spiritual values and provide private moral teaching, while ceding the formation of intellectual outlook to science and philosophy, and the governance of public conduct to secular political institutions. In addition, it became the business of Jewish religious institutions to maintain Jewish identity in a new, purportedly integrated society where there was a marked tendency for Jews to assimilate and disappear completely into the general population.

The modern Jewish religious movements of Western Europe made an additional accommodation. Traditionally, Judaism was a complex phenomenon combining religious and national characteristics. In the new, modern nation-states of England, France, and Germany, there was no room for the national dimension of Jewish existence, as it competed with the national identities of the host nations. Jews had to redefine Judaism as solely a "religion" in order to be able to fit into their respective nations as "Englishmen/Frenchmen/Germans of the Jewish religious persuasion." This was a reduction of their Jewish identity to merely "religious" in order to be able to fit the secular identity of "English/French/German." Thus, paradoxically, stressing the purely religious identity of Judaism aided them in secularization.

The Rise of Secular Jewish Movements

From the 1880s to the 1920s, several movements (especially Zionism, Diaspora autonomism, Yiddishism, and Bundism) arose in Jewish life that asserted for the first time in history that it was possible to foster a Jewish group existence without religion. This period can be viewed as the heyday of Jewish secularism (See Biale 2011).

Historically, the roots of Jewish secularism may be traced to a bifurcation in the general European Enlightenment. The more religiously conservative Enlightenment thinkers – Leibnitz, Rousseau, Kant – saw a positive place for Christian faith in such an outlook. The more radical – Voltaire, Diderot, Condorcet – sought to supersede Christianity and relegate it to the unenlightened past. In the nineteenth century, advanced thinkers, such as the left-Hegelians and positivists (Comte, Mill, Spencer), progressed to full-blown atheism, a tendency that was fed intellectually by the advance of science (especially Darwinian evolutionist theory) in the course of the century.

Structural political differences between Western and Eastern Europe also fostered differences in Jewish intellectual development. Whereas unified nation-states were at least

a feasible ideal (if not quite a perfected reality) in Western Europe, Eastern Europe was dominated by multinational empires. By the latter half of the nineteenth century, the smaller nationalities within the Austrian, Russian, and Ottoman Empires were already moving toward demanding self-determination and autonomy. It, thus, made political sense, instead of demanding to be “a Russian national of the Jewish faith,” to demand “Jewish national rights” alongside and in tandem with the national rights of Poles, Lithuanians, Ukrainians, Czechs, Slovaks, Hungarians, etc.

There was happy synergy between the religious/secular issue and the national/multinational issue. Young, modernizing Jews in Eastern Europe in the 1880s tended to be secular rather than religious in outlook, and Jewish-nationalist rather than assimilationist. Thus, whereas Western European Jews tended to be French or German in nationality and Jewish in religion, Eastern European Jews tended to affirm Jewishness as their nationality, while on the religious front they could comfortably say: “no religion.”

Zionism. Classical Zionism comprised at least three distinct types: (a) political Zionism, which strove for establishment of a political Jewish state, for the protection of world Jewry, with no preconceptions as to its cultural identity or religious identity; (b) secular cultural Zionism, which sought return of Jews to their homeland and building a Hebrew-speaking society that would spearhead a Jewish cultural renaissance; and (c) religious Zionism, which sought establishment of a Jewish society in the land of Israel that would be observantly Jewish in its religious complexion. Of these, the second is the clearest example of a secular Jewish national movement in the sense we are describing (See Hertzberg 1959). The chief spokesmen of this variety of Zionism were Ahad Ha-Am, Hayyim Nachman Bialik, Aaron David Gordon, and Berl Katzelnenson. All these agreed on the following principles (which may be styled the principles of “conservative secular Zionism”):

1. Traditional religion is no longer viable as a basis of social consensus; hence, any new Jewish social consensus or group program

must proceed irrespective of religious belief or practice.

2. Though the contents of Jewish group life in the past were formulated under a religious rubric, they are not essentially religious. At least a large portion of those contents can be reframed secularly as ethical teachings and cultural practices.
3. The Jews continue to remain a group in the modern world after the decline of religion. The basis of that continuity is national and cultural.
4. The preferred national language to serve as the basis of Jewish cultural continuity is Hebrew.
5. The preferred location for Jewish national existence and cultural renewal is the Land of Israel.
6. The renewed Jewish national culture should exhibit continuity with the Jewish past (including the Biblical, rabbinic, and medieval legacies) insofar as is possible with the rejection of formal religion. Such modes of continuity may include celebrating traditional Jewish holidays in secularized form; maintaining the validity of traditional Jewish ethical models; and adopting traditional Jewish literary sources as models for inspiration of modern Jewish literature.

To the previous thinkers must be added another group, who may be styled “radical secular Zionists,” including such thinkers as Micah Joseph Berdichevsky, Joseph Hayyim Brenner, and Jacob Klatzkin. The thinkers of this group agreed with principles #1–#5 of the above list but differed sharply with #6. In its place, they would assert:

7. The renewed Jewish national culture should be free to express the existential values of present-day Jews without regard for previous Jewish legacies, with the possible exception of the Biblical legacy. Indeed, rebellion against the rabbinic and Diaspora legacies (including some of their ethical formulations) is perhaps mandatory as a prerequisite for asserting a healthy modern Jewish national identity.

The debate between the conservative and radical Zionists came to famous formulation in Ahad Ha-Am’s essay, “Transvaluation of Values”

(1898), in which he argued for the ongoing validity of traditional ethical values against the younger generation of Zionist Nietzscheans. Nevertheless, this debate was conducted on a common basis of both sides accepting the fact of secularization (Principle #1).

Autonomism. The historian Simon Dubnow formulated an ideology which he dubbed “autonomism” that agreed with points #1–#3 and to some extent with point #6 of the conservative cultural Zionist platform but disagreed with #4 and #5. Dubnow maintained, on the basis of his detailed study of Jewish history, that Jews historically exhibited the characteristics of a national group, including limited self-government (or “autonomy”), despite their lack of complete political independence or exclusive possession of a territorial homeland. In place of #4–#5 Dubnow would stipulate:

8. The Jews have historically expressed their national culture in a wide variety of languages – Hebrew, Aramaic, Judeo-Arabic, Judeo-Spanish (Ladino), Judeo-German (Yiddish), and others. Today they may continue to express it in the traditional Jewish languages still in use, as well as in the modern languages of their host nations (Russian, German, French, and English).
9. Aside from the impracticality (around 1910) of establishing a Jewish homeland in the Land of Israel, the Jews have an opportunity to demonstrate to the world the ethical superiority of a nationalism that does not require its own territory, and will therefore never need to fight wars on its behalf.

Yiddishism. In Polish-Russian Jewry from the 1860s onward, Jewish writers started developing a modern vernacular literature in Yiddish, which started from portraying traditional religious Jewish society in a mixed sympathetic-satirical vein and progressed over the next generations into a full-fledged exploration of modes of Jewish consciousness that reflected modern European and American culture on every level and with every degree of modernist secular assertion (See Howe 1976). Several of these writers (particularly Yehudah Leib Peretz and Chaim Zhitlovsky, with the collaboration of Nathan

Birnbaum who was not himself a Yiddish writer) articulated an explicit nationalist platform, which affirmed a Jewish national identity with Yiddish as its language. This platform was formally articulated in the Yiddish Language Conference held in Czernowitz in August 1908 (see Weiser and Fogel 2010). It can be formally defined as an adoption of Dubnow’s “autonomist” principles, with the additional principle:

10. For Ashkenazic Jews, growing up speaking Yiddish, the Yiddish language is (a/the) preferred language of national-cultural expression.

Bundism. In the 1890s in Eastern Europe, young Jews who had joined the socialist movement started organizing activity among working-class Jews. Initially, they used the Yiddish language for practical purposes, for purposes of propaganda. The permissibility of affirming Jewish national-cultural identity within the context of an internationalist socialist movement was first denied, then debated, and finally affirmed. At the same time, joint affirmation of a Jewish cultural legacy and universalist socialist principles evolved into an affirmation that there was some intrinsic connection between them – the Jewish legacy was selectively interpreted to support the affirmation of socialism as a modern consequence of Biblical ethical ideals. (A similar selective appropriation of Jewish traditional values took place in the socialist wing of the Zionist movement.) To the foregoing principles of Autonomism and Yiddishism, Bundism would therefore add:

11. There is an intrinsic affinity between the ethical values of the Jewish tradition (appropriated in secular vein) and the political values of the movement to which we adhere (in this case, socialist, but other secular Jews might fill in the blank with a different political or cultural ideology).

Unaffiliated Secular Jews

From the start of the Enlightenment-Emancipation period, there were individual Jews who did not identify with any of the Jewish

religious movements or secular Jewish ideologies, yet who were identifiably Jewish in their own eyes or the eyes of others, and who expressed in their creative, social, and political achievements values around whom debate has persisted, whether to call them characteristically “Jewish” or not (Principle #11 in another context). On the grid of this discussion, they may be regarded as the most “secular” of all, as they have “liberated” themselves not only of religious tenets but also of the tenet (derived similarly from Jewish tradition) that Jews ought to constitute themselves as a Jewish group for the sake of doing Jewish things together in concert. Though these Jews might agree in part with Principles #1–#2 of the secular Jewish ideology as defined above, they explicitly dissent from #3.

One of the prototypes of this ultimate “secular” Jew was Heinrich Heine. He exhibited the “marginality” praised by Isaac Deutscher (1968) in an impressive number of ways. Though associated for a while with Leopold Zunz’s *Verein für Cultur und Wissenschaft der Juden*, he maintained no further Jewish group affiliations after becoming baptized in 1825 (which he underwent for the purpose of qualifying for a law career which he thereafter did not pursue). Identifying as a German poet, he was expelled from German lands on account of his radical political stands (but he thereafter sharply criticized his erstwhile political comrades). He settled in Paris and reported on French politics for the German journals and on German philosophy and literature for the French press. In an essay on fellow-ex-Jewish radical Ludwig Börne, he defined “Hellene” and “Nazarene” as two opposing types that included religious, esthetic, ethical, cultural, and political dimensions – a typology that was later explicitly acknowledged by Matthew Arnold as one of the sources of his philosophy of “Hebraism” and “Hellenism.” Though Heine identified polemically in this and other writings of his middle period with the “Hellene” and against the “Nazarene,” he reverted to the opposite identification during his last years when he laid bedridden from a paralytic illness, reading the Bible and praising Moses as the artist par excellence who created the Jewish

people – more durable than the Pyramids – and anticipated socialism in the Jubilee law.

Deutscher expresses a common modern folklore (as well as giving vent to his own preferences) by naming Spinoza, Heine, Marx, Rosa Luxemburg, Trotsky, and Freud as exemplars of this class of “non-Jewish” Jew. Mosse (1985) shows that in the heyday of German Jews constituting a subculture of universalist-conceived *Geist* within the larger German culture, they spanned the political gamut and included such figures as the *Völkisch* Wasserman, the nonpolitical Kafka, and the esthete Aby Warburg. What they all had in common, though, was that they followed no rules except the inner rules of their own vision, which differed from one to the next. As all principles were debatable, it may be better to speak of common “themes” characteristic of this group:

12. Whether one thinks of oneself as “Jewish” or is regarded as positively Jewish by others comes and goes mysteriously, but is often worth discussing. Often the non-Jewish Jew becomes more Jewish posthumously.
13. Judaism as religion is passé; but what Judaism “really” represents beyond any formal religious definition – whether ethically, socially, politically, culturally, or esthetically – may be of intense interest (and the focus of irresolvable debates).
14. The non-Jewish Jew generally prizes universalism over particularism. This penchant for universalism is sometimes viewed as the antithesis of religious or Zionist parochialism, or alternately as the true essence of Judaism at its best. And yet – in his private moments sometimes the particularist Jewish self-asserts itself after all; Freud belonged to the Bnai Brith, and Einstein embraced Zionism (See Yerushalmi 1991).
15. Though “organized” religion is off-limits, it is certainly permissible to seek “the spiritual” under various guises – even occasionally under the name of “God” – as long as one does so nondogmatically and with openness to insight from any source, whether from science, art, literature, philosophy, or the total ensemble of the world’s spiritual traditions.

Conclusion

It should be evident from the above survey that there are an almost inexhaustible range of relations, combinations, and variations of the terms “secularism” and “Judaism” taken together. For example:

World: “Secular” by definition is world-affirming; Judaism as a religion varies from being more world-affirming or less world-affirming (more ascetic) but is rarely world-denying.

Human being: Classic religious Judaism defines the human being preeminently in relation to God; secularism defines the human being as autonomous, but religious Judaism recognizes a certain degree of human autonomy.

Life and death: Classic religious Judaism has variable notions of afterlife, but even in its other worldly variants affirms the value of this life; secularism is centered on this life. Though there is a difference of emphasis here, it is a matter of degree.

Reality: Classic religious Judaism recognizes the reality of the present world and the *real* existence of a transcendent realm; secularism recognizes the reality of the present world and the importance of transcendent values with *ideal* existence in the human mind; though there is a difference here, the possibility of translation from one to the other is evident.

Knowledge: Religious Judaism in its rabbinic and (even more) in its philosophical forms recognized the validity of knowledge from secular sources (philosophy and science), and confronted the task of mediating between it and knowledge from revealed religious sources. Secularism recognizes only the secular sources as providing objective knowledge, but in its moderate forms is receptive to religious sources, critically examined, as sources of subjective human wisdom. Also, as we saw, the secular Jewish movements were receptive to the traditional Jewish sources, approached secularly, as models for developing modern cultural Jewish identity. The chief difference here is which sources of knowledge are considered authoritative: for traditional Judaism,

the religious tradition is the primary authoritative source, and for secularism, modern science.

Truth: For classical religious Judaism, God is the primary source of truth, and the Torah the primary vehicle, but reason is an important secondary criterion, and the findings of reason and revelation must ultimately agree. For secularism, reason (and the associated tradition of science based on observation and rational analysis) is the only reliable criterion of truth; though truth may arrive from other sources, it must pass the bar of reason in order to be certified as truth.

Perception: Biblical man “sees” and “hears” the evidences of God’s revelation. For Saadia Gaon, there were four sources of knowledge: sensation, rational intuition, deduction, and revelation, all of which agreed. In modern secular epistemology, sensual perception is the base of the hierarchy of knowledge, and all depends on it; claims to revelation are suspect.

Time: The religious outlook divides all time into three phases: creation (the origin of all things), history, and eschatology (the end of days when all will be made perfect under God’s rule). Some secular outlooks (such as Marxism and the visionary forms of Zionism – Moses Hess is a middle link between the two) adopt a similar eschatological outlook, though without God. On the other hand, some traditional religious thinkers (like Maimonides) anticipated some of the sobriety of post-modernist secularism, that even if the Messiah comes, the order of nature, with life, illness, and death will remain fundamentally unchanged.

Consciousness: (1) Metaphysically, the religious outlook posits a fundamental difference between conscious, rational human existence and the inert existence of inanimate nature. The secular outlook (following Spinoza, who is a key figure in the transition to the modern outlook here) sees more continuity between conscious and nonconscious being. Contemporary religious apologists minimize the distinction between body and soul especially in Biblical thought, but it cannot be eradicated. (2) All outlooks, ancient and modern,

recognize the distinction between ordinary and heightened modes of consciousness. The word “inspiration” has a metaphorical sense for Maslowian “peak experience” or artistic creativity, and a literal sense for Biblical thought (“the *spirit* of God rested on him, and he prophesied”).

Rationality/reason: *Hokhmah* (“wisdom”) is a positive value in all the strata of the Biblical corpus, as well as in rabbinic thought. Rabbinic thought also recognized *sevara*, the power of independent human reasoning distinct from revelation. The philosophical tradition in medieval Judaism recognized the validity of secular philosophical reasoning and tried to mediate between it and the revealed tradition. In modern secularism, reason becomes the sole arbiter of truth; however, it is possible that some of the traditions of the past will pass through the sieve of that arbitration and come out validated, or prove necessary for providing cultural identity and ethical values.

Mystery: One of the interesting debates in modern Jewish scholarship (initiated by Gershom Scholem and his disciples) is to what extent the mystical tradition of kabbalah was a minor underground current in “normative/mainstream” Judaism, and to what extent it was itself an essential part of the mainstream, creating many of the typical and abiding values of Judaism. Modern Jewish theology replicates this debate in the dichotomy between theologians of a more rationalist bent (Kaplan, Soloveitchik, Levinas) and others of a more mystical bent (Buber, Heschel, Green). As for secular culture itself, one must distinguish between a tradition running from the Enlightenment through positivism and modern analytical and scientifically based thought, versus a countertradition running from the Renaissance mystics (such as Boehme) through Pascal, the Romantics, Surrealism and existentialism. Neither religion nor secularism has a monopoly on rationalism or on mystery.

The Common Legacy of Judaism and Secularism. Today’s Jew finds himself at the end of 3000+ years of Judaism and 200 years of secularization, with all the above-described variations

and combinations played out. The freedom to choose from all these varieties and concepts is by itself a part of the secular legacy, which values openness and freedom. The insistent sense of imperative – if it is present – is a part of the Jewish legacy. Ultimately it is up to each Jew – if he or she chooses – to select the combination of elements from each of the legacies to construct one’s outlook and value-orientation. If (as the foregoing seeks to illustrate) the Jewish and the secular share a considerable overlap, though with difference of emphasis, the final result of such a process may very likely end up deserving both the descriptions “Jewish” and “secular.”

Definitions

Secularism is an attitude or political ideology aiming to eradicate religion from public and social life, or at least regulate and control religion, and especially limit its influence on state politics. *Secularity* is a condition where religion is absent from specific areas of society, e.g., state and public sphere, and/or the minds and practices of people. Secularity in specific political and public spheres may be caused by a specific politics of secularism or by the need of politics with state neutrality in terms of religion in a society with several competing religions. *Secularization* is a complex historical process, especially known from Western Europe (Davie 2002), often leading to (and partly caused by) politics of secularism. For society, secularization means that the overarching and, as it often seems, the transcendent religious system are reduced to a subsystem or a marginal dimension of cultural identity in a functionally differentiated society. For the individual, secularization means moving from a religiously authorized, integrated world to, *pace* Weber, a “disenchanted” world. Secularization often develops along with weak and broken horizons for human identity and

ambivalent interpretations of crucial experiences and the meaning of human existence. In certain areas (though so far in only a few) that may be signifying the end result, religious traditions finally disappear.

The Latin word *saeculum* means an amount of time, an age, or a century. Not least after the introduction of the clock in the twelfth century, time could be checked without listening to the religious bells of the monasteries and churches. At the Reformation, the transfer of (Catholic) church property to (Protestant) princes was called secularization. Since then, the word has been used to describe hundreds of similar processes in many areas – at state, institutional, and individual levels.

Secularism and Secularity

It has been argued that the major clash today is between religiously grounded civilizations (Huntington 1996) – or conversely between hopeful Asian, humiliated Middle Eastern, and frightened Western, especially European, cultures (Moïsi 2008). However, an equally serious clash, based on an almost total lack of mutual understanding, is that between religious and secular cultures or between secular and religious elements in the cultures of the world (Juergensmeyer 2003).

In the second half of twentieth century, the world was inhabited by (religious) Indians and ruled by (secular) Swedes as Peter L. Berger has put it (Berger et al. 1999). In spite of the personal religious commitment of various American presidents and their different religious-political rhetoric, the politics of the world in the twentieth century was governed by secular minds. In the index of former US Secretary of State Henry Kissinger’s masterpiece on statesmanship, *Diplomacy* published in 1994, the word “religion” does not appear even once. Today, such an omission ought no longer to be possible – even among secular political scientists.

Over the last 30 years, the relation between politics and religion has been changing. In the 1980s, the three Abrahamic religions became

more visible in politics, with Menachem Begin from the Likud Party winning elections over the more secular Labor Party in Israel in 1977, anticommunist Polish Cardinal Karol Wojtyła being elected pope in 1978, Ayatollah Khomeini seizing power in Iran, and the Moral Majority being formed in the USA in 1979. The fall of the Berlin wall in 1989 outdated the focus on conflicts between East and West and created space for what some have called the clash of civilizations: the September 11, 2001, attack on the twin towers in New York by radical Islamists and Muslim protests against the Danish Muhammad cartoons, published in *Jyllands-Posten* on September 30, 2005, to name but two.

Especially in the case of Denmark, it is obvious that it is not the role of religion in the life of the people that has been changed. On the contrary, what has been changed and what has caused the overheated political debate on religion is its role in the modern politics of symbols. In three major Danish newspapers, the debate on religion covered 25% of all public opinion material in 2005 – in one of the world's most secularized countries!

Much of the turbulence around the role of religion in politics – and the politics of secularism – is linked to the fact that European politics of secularism often rest on historical myths. The 1648 Peace of Westphalia recognized the principle from the 1555 Peace of Augsburg, by which the princes gained the right to determine the religion (s) of their own state (*cuius regio, eius religio*). It is a myth, however, that the European wars between 1618 and 1848 were “religious wars,” in which it was religious differences that caused the states to fight. They were rather wars through which European national states were reestablished, supporting themselves with the aid of state religions. Another myth is the idea that democracy in Europe developed after Christianity and secularization had already led to a state of secularity, even though it was often Christian conservative parties that promoted democracy (and were themselves secularized in the process). In the same way, the six countries, Germany, France, Italy, and the Benelux countries, the original signatories to the treaty of the European Economic Community in 1957, were

all influenced by Christian politicians. Democracy did not come about as a result of secularism (Christoffersen). Rather, democracy together with other factors led to the politics of secularism and the process of secularization in Europe, which, however, has not so far been followed by a similar process *outside* Europe, where many forms of rapid modernization are taking place without the accompanying secularization that has been the dominant pattern in Europe.

Where we have seen new attempts by religious leaders or religiously defined groups to take over or dominate political power in other parts of the world, not least after 1979, in Europe, the so-called return of religion in the public sphere most often resembles the old European tradition with the nation-states using religion as a tool to support and legitimize themselves. In a number of European countries, the state's legitimization of civil religion is practiced (e.g., Britain), while in other countries such as Denmark civil religious practices have become more visible (e.g., in memorial services for soldiers). As the state seems to have no heart as such, it sometimes uses churches to express popular feelings linked to certain national affairs. France, with its strong principle of separation of church and state (*laïcité*) since 1905, is at one and the same time limiting the visible presence of religion in public places such as schools, yet promoting a National Islamic Council, and this is happening in a situation where the place of religion has switched radically from a principle of heteronomy to that of politics of identity, supporting individuals and minorities in an uncertain modern society. By listening to the public voices of religious leaders and sometimes even negotiating with them, President Sarkozy and other European politicians act as secular leaders attempting to integrate religious minorities in a democratic society, though they are far from ascribing any right of domination to these leaders.

In similar ways, the politics of secularism are manifold and complicated around the world, depending for instance on the state of secularity in the population and the process of secularization – or the absence of such a process. Principles of secularism, e.g., the independence of state government from religious influence, are found

in the constitutions of religious countries as widely diverse as the USA, India, Pakistan, and even Iran (Christoffersen 2006). In all cases – and most obviously in the USA with its “wall of separation” between church and state – the actual influence of religious forces on state politics is inevitable, such as when democratic elections of MPs and presidents for secular politics depend on religious affiliations and support.

It was said of Turkish writer Orhan Pamuk when he was awarded the Nobel Prize for Literature, 2006, “in the quest for the melancholic soul of his native city (he) has discovered new symbols for the clash and interlacing of cultures.” As cultures are increasingly interlacing with one another, religions are interlacing with all sorts of dimensions of our societies in what seem unpredictable ways. For this reason, to describe the relationship between religion and its surroundings, the term *intertwinement* has been coined as being more appropriate than *separation*. Religion is adoptable, adaptable, and potentially everywhere available. Religion may mean and do almost anything, including absolutely nothing. It is often hard to *include* religion in the discourse, but it is also often hard to *exclude* it. What may be achieved in the politics of secularism is at best a *regulation* of the ways in which religions function in our societies.

Secularization

There are no metaphysical laws determining the historical process of secularization. If we take secularization to mean a process leading to *secularity* as a condition where religion is removed from specific areas of society, e.g., the public sphere, then secularization is promoted and more or less determined by state politics (Riesebrodt 2007:244–253). This is so even if religious traditions throughout the world refuse to see themselves as privatized and marginal in society. In sociology of religion, *differentiation of spheres in society* is the dominant definition of secularization. Another common definition emphasizes *the regression of religious beliefs and practices among common people in daily life*.

In both senses of the word, Western Europe – as Grace Davie has argued – is the primary and almost only example of significant secularization. In recent years, the debate, especially among sociologists of religion, has focused on the direction of the secularization process: Is it going to continue until the full disappearance of religion, as argued by Karl Marx and Max Weber? Or has it stopped at the present level? Or, indeed, has it been turned into its opposite in a process of “desecularization”? Or is the place of more or less institutionalized and socially integrated religion being taken over by new and freer forms of *spirituality* after “the massive subjective turn in modern culture” (Heelas 2006)?

The Canadian historian and philosopher Charles Taylor has created a new point of departure for interdisciplinary discussion about secularization in his *opus magnum* from 2007, *A Secular Age*, where, through integrating what has been documented and debated in several disciplines in recent decades, he combines a historical account of the secularization of cultural and social life in Western societies with an examination of the conditions for the personal experiences of, and search for, religious or nonreligious existential self-understanding and practices in the secular age of Western societies.

The historical process of secularization in Europe has passed through a number of phases. Taylor points firstly to the *Reformation* when the hierarchy of holiness is broken, access to God is “democratized” through the individualization of faith and salvation, and finally, the Church is subject to reform by mortals (*ecclesia semper reformanda*) – as indeed hereafter are all sorts of institutions in society. Next comes the idea of *modern civility*, making room for a society based on common culture and manners supported by a rational interpretation of the laws of nature and with the downplaying of irrational antistructures to authorized religion such as carnivals. Next, Taylor points to the long age of *Deism*, where the new trinity is God as destiny, virtue as the golden mean, and eternal life compounded of an eternal soul, the impersonal laws of nature, and art as produced by human creativity (and no longer by imitating God’s

creation). Along comes also *humanism*, which promotes the ideas of the absolute value of the individual human being and of universalism from Christianity, both freed from their connections to God and the Christian faith. The age of *mobilization* changes the established churches into denominations for the individual to choose among, the common backdrop for life in society breaks down, and the individual is left to be saved in the religion of their choice. Eventually, we come to the age of *authenticity*, where only what is experienced by the individual or some trustworthy first person (the author) can be believed. If we do not *feel* God, then he is dead. Conversely, if traditions and practices where God is alive are experienced as authentic, then God is alive again for that individual.

For Taylor, the process of secularization has especially three lines of development. Most fundamental is (1) *disembodiment*, *social disembeddedness*, and thereby, the *excarnation* of religion. In the constitution of human individuals, Taylor at the same time finds (2) a shift from *porous selves*, which may allow themselves to be invaded by religious powers, to *buffered selves*, which control their own relations to and use of, religious elements. Alongside these, he emphasizes (3) *the dissolution of holiness*, the belief that God's power is somehow concentrated in certain people, times, places, or acts. Being secularized – and not just old-fashioned religious or newly spiritualized – means (4) being able to experience the deep coherence and even fullness of life within *the immanent frame* where “God” at the most can be seen as the way the individual is part of the great evolutionary emergence and limited to the destiny ascribed to each of us as a part of nature. For Taylor, it is important that secularization is not primarily a disenchantment of life (as in Weber) but a very real transformation of human and thus religious life:

We have moved from an era in which religious life was more ‘embodied’, where the presence of the sacred could be enacted in ritual, or seen, felt, touched, walked towards (in pilgrimage); into one which is more “in the mind”, where the link with God passes more through our endorsing contested interpretations – for instance of our political identity as religiously defined or of God as the authority

and moral source underpinning our ethical life. (Taylor 2007: 553 f.)

The process of secularization has ended not with the *disappearance* of religion but with radically *changed conditions for relating* to religion. For society, secularization means that the overarching and, as it seems, transcendent religious system is reduced to a subsystem – to a more or less marginal dimension of culture in a functionally differentiated society. For the individual, secularization means moving from a religiously authorized, integrated world into a disenchanted world with broken horizons for human identity and ambivalent interpretations of crucial experiences and the meaning of human existence.

Taylor accepts that religion is a viable interpretation of life. So are humanism and naturalism. He considers these three as equal from a philosophical and scientific point of view. His personal view, however, is that life depends on nature and culture, within which an experience of fullness can be embodied. It is a condition for human life that we always ask for more, for transcendence:

Transcendence escapes embodiment in the sense that, on the one hand, I do not know if my present way of reaching God, understanding of God or whatever, is inadequate. It does not do justice to reality and hope that I will somehow be able to climb further. But, on the other hand, there is no way in which I will have a relation to God which is not in some way or the other embodied. It is just like when I am writing a poem and I am trying to find the right word and I feel all the time this is not the right word, but what I am trying to do is to find the right word, so there is no way for me getting that written without finding the word. (Taylor in Lombo et al. 2003)

Secularization is an integrated part of a complex historical process in Western societies, affecting human beings who are complex creatures – parts of nature but always reflecting on their own existence and place in history and nature. Secularization has changed the conditions for religious life in Western societies, but it has never made religion disappear – nor indeed has any “desecularization” made religion return – except for in specific cases and areas. Secularization cannot be adequately described as a process of subtraction, whereby religion increasingly

disappears from modern life as a result of modernity. On the contrary, it may be argued that exactly the malaises of modernity are challenging religion to *contribute* to human life in modern society. Especially in recent decades, the ethos of authenticity that originated during the Romantic age has established itself as a common condition for human beings in Western societies. The central question thus seems to be: What is experienced as “authentic”?

This is far from meaning that religion will return to a leading role in existential interpretation and practical support in the challenges of modern life. It does mean, however, that the long religious traditions which for centuries were part and parcel of our societies will remain as a common heritage to be drawn on in many areas of life – perhaps even more so in postmodern times. Jürgen Habermas, who personally believes in modernity and not in religion, puts it this way:

In the West Christianity not only fulfilled the initial cognitive conditions for modern structures of consciousness . . . Egalitarian universalism, from which sprang the ideas of freedom and social solidarity, of an autonomous conduct of life and emancipation, of the individual morality of consciousness, human rights and democracy, is the direct heir to the Judaic ethic of justice and the Christian ethic of love. This legacy, substantially unchanged, has been the object of continual critical appropriation and reinterpretation. To this day there is no alternative to it. And in light of the current challenges of a postnational constellation, we continue to draw on the substance of this heritage. Everything else is just idle postmodern talk. (Habermas 2006:150f)

Future Prospects

It is generally agreed that the processes of modernization, often combined with urbanization, rationalization, and the massive introduction of modern technologies, do not in themselves lead to secularization. Some even use the terminology that modernities can be multiple and varied, with components of religion and secularity playing all sorts of roles.

In European tradition, the main trend is still to define modernity as a culture where (1) relations to nature are pragmatic and instrumental, (2) relations

to fellow human beings are separated into public and private spheres, (3) the individual can act and see himself/herself as an autonomous being, and (4) relations to something absolute such as God depend on the choice of the individual and are only applicable in the private sphere. Often, the views of the destiny of modernity and religion are bound together. Some – in line with Marx and Weber – think that modernity is an unfinished project which will eventually lead to a full secularization. Others think that modernity in Europe for all of us is a realized condition of life which nonetheless cannot sideline religious questions and needs. In that case, the process of secularization is not likely to come to an end in any foreseeable future.

Selection Pressures

Matt Rosano

Psychology Department, Southeastern Louisiana University, Hammond, LA, USA

Environmental constraints that limit an organism's access to vital resources for survival and reproduction. These pressures are typically thought of in ecological terms such as limitations in food or shelter, or the necessity of avoiding predators. However, selection pressures can also be present in terms of access to mates, attraction preferences exhibited by mates, or social pressures that influence status within a group. These pressures are often divided into those represented by natural selection (competition for ecological resources, disease, predation etc.), sexual selection (competition for mates), and social selection (competition for social status).

Self

Consciousness; I; Mind-body; Mind-body problem; Person; Soul

When answering the questions like “what are we?” and “who am I,” the concept of self is typically

employed. In minimalist terms, a being can be described as a self when it is able to have first-person thoughts. In order to have this kind of self-experience (such as, “it is I who is looking back at me in the mirror”) in the sense that humans and some animals do, symbolic language and self-consciousness is needed. In human evolution, the turning point was the emergence of *Homo sapiens*, who had more developed cognitive functions compared to *Homo erectus* and other members of the *Homo* lineage. These capacities combined with symbolic communication enabled the recognition of oneself as “I.” Mirror tests performed on certain nonhuman, highly developed primates demonstrate that this capacity is not restricted to *Homo sapiens* alone (Hysussteen and Wiebe 2011). This alone, however, does not yet help us to fathom the ontological status of the self, that is, in what sense the self exists.

The question about the nature of self is one of the most complex issues in contemporary philosophy, science, and theology. This is due to the fact that self (like the neighboring concepts of person, ► [personhood](#), ► [consciousness](#), and ► [soul](#)) exists in the borders of multiple modes of enquiry, which all are constantly developing and changing. It would be easier to list those sciences, which do not have bearing on our understanding of the self than those that do, and even in this case the list would be very short. In addition to the vast array of sciences that all want to have their say on self, the discussion is complicated by the disagreement between the sciences, their underlying theories, methodologies and philosophies, and even political agendas.

For example, postmodern philosophers typically see the deconstruction of any stable notion of self as their ethical and therapeutic duty. This is supposed to liberate humans from external restrictions. In contrast, some scientists wish to reduce human personhood to the level studied by neuroscience and thereby purify the discourse from the purportedly vague talk of the philosophers. Where some seek to end external control, some seek to strengthen it. In both of these two cases, the means, however, are relatively same, namely, adopting a skeptical attitude toward the existence of any stable and sustained self (Strawson 2009).

Both of these options are problematic for those religious notions of self, which require stability and continuity as well as a nonreductive understanding of self, soul, and person. For example, monotheistic religions need some kind of a stable self in order to make the idea of postmortem survival internally coherent or the idea of moral progress or growth in virtues possible. Of course, self is defined differently in different religions and sometimes these interpretations are debated within the traditions themselves. Some Eastern religions deny the existence of self and regard it illusory; some consider it to be real, but only episodic. Thus the relevance of the discussion about self in the sciences and humanities for specific religions has to be decided case by case. The greatest challenge for the understanding what is meant by the concept self is that it has radically different uses in different contexts. In the following, two basic ways of using the concept are distinguished.

Where Am I?

Depending on the context, self can be approached from scientific/philosophical or existential/sociological perspectives, and naturally there is much overlap. The scientific/philosophical question is focused mainly on the location of self. If I use the word “I,” what do I refer to? Are we bodies, brains, immaterial souls, bundles of impressions, or some fusion of these, perhaps something else? Maybe there is no such thing as “I”? The heart of problem here is the difficulty to locate the *thing* that is the self. Above I gave a general, popular scientific answer to the question about what self as a concept means. These scientific/philosophical questions are more interested in the nature of the self: what kind of thing it is. The answers follow more or less the standard solutions of the ► [mind-body problem](#) in the ► [philosophy of mind](#), with the crucial distinction that the mind-body problem is about the nature of consciousness and other mental phenomena, while the question about self is about the nature of the subject of these phenomena. Choosing some

particular theory about the nature of the mind does not yet answer the question who we are as individual beings. The main ways of defining self in this context are either substantival (self is either physical or nonphysical entity) or non-substantival whence self is, as David Hume insisted, a bundle of sensations without any integrating unity (Olson 2007).

Recently, the emergence of neuroscience has had effects for the notion of self. If I detect the firing of neurons or an increase of blood pressure in some areas of the brain, does this mean that I have detected a human self? Is this event a human person? For example, Francis Crick (1995) has argued that we are “no more than the behavior of a vast assembly of nerve cells and their associated molecules.” Those who oppose this conclusion argue that Crick has committed the *mereological fallacy*: he has attributed properties of the whole being to some particular part of that being. In other words, it is *I* who feels, the person, not my brain. This is not to deny that brain is one of the central organs we need to experience pain in the first place, but pain is the property of the whole being, not just one organ.

How Did I Become Me?

The existential/sociological question requires a more practical answer. Existential considerations involve questions, such as how we see ourselves in relation to the various expectations of our culture or our own personal ideals. Sociology is, among other thing, interested in those mechanisms that shape our self-image. More deterministic theories see individual selves as mere reflections of the environment they happen to dwell in; this view is sometimes called environmentalism. In order to confront this kind of determinism, it is common to use different concepts to speak about person’s own desires and actions in contrast to self as it exists as a product of the society. This “unsocial” self brings in the element of indeterminacy. The question how much we are actually able to control how our selves are formed is open for debate (Elliot 2009).

From the existential/sociological perspective, self is the place where conflicting powers meet and clash with each other. Postmodernists usually speak about “subject” instead of self as it draws attention to being subjected to something, being influenced from the outside. Postmodern theory of the subject attacks stereotypical and frozen definitions of the self, in favor of more fluid and plural identities. The apparent paradox is that, in its radical forms, this politically motivated ideological strategy seems to make any sustained and public political action ultimately vacuous or even more subject to ambiguous use of power.

Both contemporary philosophy and psychology acknowledge the plural nature of human self-conception. We can inhabit multiple self-understandings in our lives and even at the same time. Among others, Charles Taylor and Paul Ricoeur have stressed the role of narrativity in our understanding of the self. Self is not an unchanging thing, but something that comes into being when our life is presented in the form of a narrative. This is one way we can try to have an access to an integrated self, without being able to answer all ontological questions; self just is the being that has had all these experiences. The narrative self is sometimes contrasted with the episodic self. Perhaps the best artistic portrayal of an episodic self is the representation of singer-songwriter Bob Dylan in the movie *I Am Not There* (2008), where Dylan is portrayed by different actors in a way that does not seem to form a coherent story.

Recently, Patrick McNamara (2009) has suggested that religion is an adaptation that allows us to cope with the fragmentation of the self. Religious activity helps the individual to mediate between the ideal self and current self by providing a framework, which is able to join together conflicting elements, both in individual and societal level. Ideally, religion contributes to healthy self-understanding and communal life by giving a structure to our lives. Here “religion” works as a meta-category that does not take into account particular philosophical or theological notions of self, and how self in fact appears in different traditions.

A defining feature of developmental systems that arises because dynamic interactions involve a dialectic relation between system-changing and system-constraining relations. Such a balance between changes that make the system different and changes that maintain the structure and function of the system reduces the potentially infinite complexity of the system and, as such, enables the identification of continuous instances of structure and function.

Description

The concept “self” has shifting meanings as a result of it originating in religious ideas about the soul, being heavily philosophized during the Renaissance and most recently being the topic of scientific research. The dominant contemporary definition is that self is the thoughts and images people have about themselves. Such a definition opens up the self to empirical research by asking people, in various ways, what they think about themselves. However, the self was not always conceived of as an empirical phenomenon.

The concept of the “self” grew out of religious thinking about the soul. Early thought experiments by Avicenna and Descartes tried to demonstrate that the thinking mind exists independently of all things material and thus that it belongs to the immaterial realm of the soul. Descartes was particularly influential in arguing for an ontological dualism between material and immaterial realms. In practice, this dualism was as much political as ontological. Specifically, it served the diplomatic function of legitimizing the sphere of science on the one hand and the sphere of religion on the other. While this dualism was a coup for science, in that it consolidated the domain of science as all things material, it created a problem for empirical research on the self because the self was seen to inhere in the immaterial realm.

Hume was one of the first to try to bring the self within the domain of empirical research. He argued against conceiving of the self as a spiritual

or religious concept. “Man,” Hume wrote, “is a bundle or collection of different perceptions” (Hume 1740). Thus, the self, according to Hume, is little more than the ongoing stream of thoughts, perceptions, and memory images as they are experienced. What Hume did was to take the self out of the immaterial realm of the soul and plant it firmly within experience – thus opening it up to introspective analysis. This situating of the self within phenomenological experience provided an essential platform for subsequent theorists and researchers who could then investigate, by introspection, the experience of self.

With the separation of psychology out of philosophy in the latter half of the nineteenth century came an even more determined effort to bring the self within the purview of scientific analysis. Central to this effort was William James (1890). James furthered the conceptualization of the self as an empirical thing, open to scientific analysis. Using introspection, James developed a model of the self which still provides the foundation for much contemporary scientific research on the self.

According to James, there are different levels of the empirical experience of self. At the most basic level, there is what he called the material self. This concerns the things that we can call “mine” – including our bodies, clothes, families, homes, cars, possessions, and accessories. The second level is the social self and includes the ideas and images that other people and groups have concerning us – including our parents, children, friends, colleagues, and society at large. The third level James somewhat confusingly called the spiritual self. The term spiritual reflects the religious heritage of the concept, but as James uses the term, it pertains to nothing spiritual. This third level includes our faculties of mind and habits that we identify with – our will, memory, determination, attention, moral convictions, piety, guilt, anxieties, and so on. Accordingly, it might be more appropriate to refer to this as the psychological self.

Today, there is a large and diverse scientific literature which elaborates James’ outline and proceeds to examine the various thoughts and images that people have regarding themselves.

Using a disparate set of terms, researchers examine people's self-concepts, self-representations, self-images, self-narratives, social identifications, and identities. One important finding to emerge across this research emphasizes the social nature of self. Although people are not very good at judging what other people actually think about them, there is a close connection between what people think about themselves and what they think other people think about them.

James added subtlety to the three layers of the empirical self by pointing out that each layer contains past, present, and future images. In support of this idea, research has since shown that people have a range of "possible selves" which can be central to people's sense of self even if they are not currently living out those possible selves (Markus and Nurius 1986). James emphasized that the existence of different possible selves in the past, present, and future makes possible a range of tensions within the self. This aspect of James' thinking has been developed in research on discrepancies between these images. For example, a discrepancy between someone's self-image in the present and their ideal future self-image should lead to motivation to change. Alternatively, a discrepancy between their self-image in the present and their ideal self-image could lead to depression or anxiety (Higgins 1987).

James was acutely aware of the religious and philosophic heritage of the concept of self. Accordingly, he devotes considerable analysis to the question: Is there anything beyond the material and social images of the self in the past, present, and future? Is there something "behind" these images which bind them together and which create our phenomenological experience? In short, is there anything approximating a soul?

Using introspection, James finds no evidence for anything beyond the phenomenological act of thinking and introspecting. Moreover, from the point of view of science, he argues that there is no benefit in postulating a "thinking substance" behind the thinking in order to explain the thinking. However, he does acknowledge, under the influence of Kant, that every thought about an object presupposes a thinking subject and thus that there is by definition an aspect of people's

selves that is beyond the content of the thoughts they have about themselves. James proposes to call everything which the self thinks about the self "me" and withholds the term "I" for that aspect of the self which does, or rather is, the thinking.

The three layers of the empirical self, and all the self-images in the past, present, and future, are all part of the "me" – they are self-descriptions. They cannot include the active, thinking, describing subject – the "I" component. Each thought about "me" and each act of self-regulation presupposes an "I" which is the subject of the thought or act. If the concept self were reduced to only the "me" – to self-description – then the self would be inert and inactive. Before a child has a self-narrative or self-concept, and thus before she has a "me," the child is still an active agent in the world: The "I" is active. As time passes, the baby becomes a child and develops self-descriptions, and each movement of self-awareness, each emergent self-conception puts, as it were, clothes on the naked "I" of action. First there is action, then there emerges an image of oneself acting, and then, those images begin to mediate action. But the self-images always lag behind the active component. According to James, one can never fully know oneself: The "I" of each action and thought exceeds previous self-description, thus making the self fundamentally open unto the future.

Recently, these ideas have led to research on the dialogical dynamics of the self (Aveling and Gillespie 2008). The self is conceived not only to be a system of self-images, or self-regulatory tensions between those images, but also to be a system within which there are I-positions which shape the stream of self-images but which are not themselves within that stream. The I-positions are not self-representations: Rather they are the positions from which people represent themselves. For example, someone who thinks that they are very wealthy, and prides themselves on their wealth, has, one could argue, internalized and cultivated a consumerist and materialistic I-position from which they are evaluating themselves. Alternatively, someone with a disability who stigmatizes themselves has,

arguably, internalized a negative view of others and that has become an I-position within their self. It is the position from which they stigmatize themselves. I-positions are often socially constituted through the internalization of the perspectives and discourses of others. Research has examined the contradictory tensions both between I-positions and between I-positions and self-images (Gillespie 2007).

Self, when conceptualized in common sense terms, seems to refer to something inside the person, an individual, idiosyncratic, even solipsistic thing – but it is not. As James recognized, and further research has productively elaborated – the self is deeply social. Considering first the “me,” it is social in four ways: First, each “me” image is a self-observation and on an equivalent footing to the observations we make about other people. In this sense, self-images are attributions and acts of social perception. Second, our various me images are significantly influenced by what we think other people think about us. Third, how we think about ourselves and other people is influenced by the societal roles occupied. Fourth, each culture provides a range of collectively created and historical images, some idealized and others scorned. In this way, each of us constructs our own self-images out of the cultural templates and narrative tropes that we are offered within our cultural milieu. Turning now to the “I,” it is social in a different sense: It is a set of socialized practices, tendencies, impulses, and habits. These habits of thought often correspond to the thoughts of others, and as such, when we adopt an I-position, we are in fact often taking the perspective of others.

If the self is social rather than spiritual, that opens it to change. We should expect that as society changes, so people’s selves will change. New self-images and new I-positions should become available, and new values link them together creating new ideal self-images and thus new impulses for self-regulation. But it is important to emphasize that people are not the passive objects of societal and cultural change. Rather, they are agents within the change process.

To study this self-constitutive process, Foucault (1988) introduced the concept of

technologies of the self. Technologies of the self are means which we use to act upon ourselves. Religions, much of psychology, and many cultural practices can be thought of as social technologies aimed at reconstituting selves. For example, Buddhism offers meditations and practices for breaking down the attachments and desires of the self. Consumerism, on the other hand, promises retail therapy through cultivating and satisfying people’s attachments to products. Both are technologies of the self, and clearly they constitute very different selves. The list of technologies of the self is long: Each therapeutic practice, many religious practices, many institutional regulatory practices, and many common sense strategies of self-control are part of the processes through which selves reconstitute themselves. Contemporary societies are characterized by a proliferation of possible selves, and even contradictory self-ideals, combined with a wide range of techniques for cultivating the desired self-image. Today, Gergen (1991) argues, we are becoming “postmodern selves” – swimming in a sea of media images and communication technologies, which enable us to cultivate and live out many disparate aspects of our selves. This tradition of research is distinctive, in that the self is not something to be discovered and described, rather it is something that is made and remade.

Our conceptualization of the self has changed as the concept has moved from the domain of religion, through philosophy, to the domain of science. But, it is not only our conceptualization of the self which has changed, what the self is has also changed. Each conceptualization of the self entails different normative ideals (Markus and Nurius 1986) which have been used to guide our educational activities, socialization practices, and personal techniques of self-regulation. That is to say, different societies at different points in time have created different selves. The mechanisms of self-creation are societal institutions and technologies. Realizing this reflexive and fundamentally cultural and historical aspect of the self gives us an obligation to conceptualize the self in such a way as to open up, rather than close down, new domains in which the self can be cultivated and performed.

Self-Actualization

Sarah A. Schnitker¹ and Robert A. Emmons²

¹School of Psychology, Fuller Theological Seminary, Pasadena, CA, USA

²Psychology Department, University of California, Davis, Davis, CA, USA

As utilized by Abraham Maslow, self-actualization refers to the full realization of a person's potential. Placed at the top of Maslow's need hierarchy,

self-actualization was postulated as possible once the lower basic and meta needs of the self were met. Of particular importance, self-actualization is perceived to be motivated by the intrinsic desire for growth in the person, whereas more basic needs are motivated by deficiencies.

Semantics

Dennis Bielfeldt

South Dakota State University, Brookings, SD, USA

Description

A great many things possess meaning, e.g., thoughts, actions, gestures, natural objects, cultural artifacts, and linguistic expressions. Although all have meaning, some bear logical relationships and some do not. Clearly, while relations of synonymy (sameness of meaning),

antonymy (oppositeness of meaning), hyponymy (meaning inclusion), homonymy (same words/different meanings), analyticity (truth by virtue of meaning alone), entailment (whenever A is true, B is also true), logical truth (B follows necessarily from A), and equivalency (B follows necessarily from A and vice versa) obtain among linguistic expressions, they are not present in religious rites, hadrons, paintings, or storm clouds. Although both kinds of objects have meaning, they do not have it in the same sense. Theories of semantics arise principally in response to questions about meaning of the second variety: How do linguistic expressions gain and bear meaning?

The term “semantics” derives from the Greek adjective “*semantikos*” meaning “significant.” While philosophers have always been interested in semantic questions (especially Plato, Aristotle, the Stoics, Augustine, medieval philosophers generally, Hobbes, Locke, Leibniz, Berkeley, Hume, Mill, Peirce, etc.), semantics has been more deeply explored since the 1879 publication of Frege’s *Begriffsschrift*. While semantics has been traditionally studied within philosophy, since the late 1960s it has been increasingly explored within linguistics proper, where it is now investigated alongside of syntax, morphology, and phonology. One can distinguish within semantics the analytical study of artificial languages from the empirical investigation of natural languages. While the first seeks to provide an unambiguous interpretation or model for formal languages, the second aims to grasp the relations between terms and their meanings already present within natural languages.

Semantics is one of the three branches of semiotics (the study of signs), the other two being syntax and pragmatics. While syntax concerns relations among linguistic symbols, and pragmatics relations of uttering, using, responding, etc., to extralinguistic entities where the intention of the speaker, linguistic ability, belief, audience, and context of use are crucial, semantics deals with the relations of referring, denoting, and connoting extralinguistic objects generally. Semantic theories may be broadly divided among theories of meaning (connoting

and intension), theories of reference (denoting and extension), theories which combine elements of both, and pragmatic theories taking meaning to be the use made of an expression by interactive participants.

Of fundamental importance in semantics is the distinction between an expression’s extension and intension. Intuitively, the intension of an expression is simply its meaning (or concept) and the extension what is “picked out” by that meaning. More specifically, the extension of a singular term is its reference, of a general term the collection of things to which that term applies, and of a sentence its truth-value. Alternately, the intension of a singular term is its sense, of a general term the property or relation so expressed, and of a sentence the asserted proposition.

Extensionality applies if and only if the substitution of one term (or predicate) by another having the same referent does not change the truth-value of the sentence under question. Consider the following where “ $\Box$ ” means “necessarily”:

1. $\Box(9 > 7)$
2. The number of planets = 9
3. Thus, $\Box$ (the number of planets > 7)

The argument is clearly invalid because (1) and (2) are true while (3) is false. But what went wrong? Even though “the number of planets” and “9” have the same extension (the number nine), substitution of one for the other within a context of necessity (a “modal” context) does not preserve truth, and thus the context is intensional. In addition to modal contexts, intensionality also characterizes quotations, indirect speech, propositional attitudes (e.g., “believing that” or “knowing that”), intentional constructions (e.g., “looking for” or “wishing for”), and temporal designations. While extensional semantics has been enormously successful within formal languages, it has proven less so for natural languages. For instance, while the extension of “is a unicorn” and “is a ghost” is the same (both designate the empty set), natural language wants to be able to say “S believes that y is a unicorn” is true and “S believes that y is a ghost” is false.

Theories of meaning and theories of reference are framed to account for different sorts of things. Meaning, theories attempt to explain notions of synonymy, analyticity, entailment, intensional contexts, intentionality, and meaning inclusion, and thus appeal to sense, meaning, semantic markers, and lexical entry. Such theories employ a componential analysis in which the meaning of words is decomposable into more primitive semantic markers. Meaning theories can be divided further into atomic theories precluding analyticity and molecular theories presupposing it. On the other hand, extensional theories of reference extend to truth conditions – logical, necessary, and contingent truth – and entailment and therefore appeal to reference, denotation, satisfaction, truth, models, and possible worlds. An advantage of theories of reference is that they seem ontologically simpler, for one need not posit the existence of meaning entities. In addition, one can distinguish internalist and externalist semantic theories. While the former understands the semantic relation as holding between language and “what goes on in the head,” the latter asserts a relationship between linguistic expressions and the world.

Another group of theories argues that the conceptual role of expressions and mental states are most important in understanding semantics. “Conceptual role semantics” (sometimes called “functional role semantics” or “procedural semantics”) are related to the pragmatic attitude of the later Wittgenstein, whose “meaning as use” approach supposes that meaning must be understood functionally. Conceptual role semantics thus claims that the meaning of linguistic expressions and the content of mental states is determined by the role played by them. The theory is applicable both to language in an ordinary sense and to mental representations – either as part of a “language of thought” or as mental states generally. Because the theory denies that thoughts have intrinsic content prior to their functional use, meaning, and content derive from use, not vice versa.

While broadly speaking, conceptual role semantics claims that the content of linguistic symbols or mental states is determined by use,

more narrowly, conceptual role semantics asserts that the content is determined by symbols or mental states within inferential mental processes. Simply put, the meaning of a sentence is fixed by its place within the network of the inferences it legitimates. (Fodor calls theories of this kind “inferential role semantics.”) While the relevant “uses” which determine meaning generally in conceptual role approaches include perceptual input, internal thinking, and behavioral output, another class of (information-based) semantic theories claim that a symbol’s content rests solely upon the first of these uses: information about the environment carried by the symbol’s internal tokening.

Self-Identification

Science

While philosophical semantics explores what it is about language, persons, and the world that makes words and thoughts have meaning, linguistic semantics concerns itself primarily with the empirical question of how the meaning of particular expressions contribute to the meaning of larger ones. Just as physics starts with natural objects and properties and explains their interrelationships without advocating a philosophical ontology, so too linguistics seeks to explicate the interrelationships of linguistic meaning without ontological prejudgment. Although this is the goal, philosophical issues arise frequently in the work of contemporary linguistic semantics, a fact that is not surprising given the role philosophers have played in the area.

Since semantics is part of linguistics, and linguistics explores linguistic competence by investigating the innate endowment of human beings to speak a language, linguistics (and thus also semantics) is sometimes thought to be a special domain within psychology. Chomsky, for instance, speaks of “I-grammar,” an internalized grammar having the components of phonology (rules telling how to pronounce expressions), syntax, and semantics. By virtue of this I-grammar, humans have an ability to acquire linguistic capacity; they possess a “language acquisition device” which explains

how they can learn a grammar though they have a poverty of stimulus.

Chomsky and followers argue “mentalist” theories of language against behaviorist methodologies that understand human linguistic behavior without appeal to internal states. Their mentalist theories were generally internalist in that they presupposed what Putnam calls “the principle of methodological solipsism,” the notion that psychological states do not presuppose the existence of individuals external to the subject. Each speaker has her own internalized grammar, I-grammar, which is intensional, individual, and internal. While internal mentalist theories hold that speaker grammatical competence can be accounted for without postulating anything external to grammatical states, external mentalist theories claim that while each person has an internal representation, there is yet a relation between elements in the person’s I-grammar and external objects. The nature of this relationship is a topic of some dispute. One option groups the I-grammars of individuals into resemblance classes; another holds that individual I-grammars token an I-grammar type. Critics have claimed that the ability of humans to learn language is accounted for on the basis of a general learning ability and not on the basis of a special linguistic-acquisition device. Others argue that the science of semantics need not appeal to internal representations at all.

Extremely important for the development of linguistic semantics is the pioneering work of Tarski’s student, Richard Montague, who rejected a theoretical difference between formal and natural languages. In denying that natural languages were too unruly to be formalized, he claimed that both syntax and semantics could be grasped algebraically, and a homomorphism maps the elements of syntactic algebra onto the elements of semantic algebra. In his formal semantics, Montague showed how the compositionality of syntax could map to a corresponding compositionality of semantics. Because syntactic rules put expressions together to form expressions, corresponding semantic wholes can be decomposed into more primitive parts.

The work of Katz should also be mentioned. His acute sensitivity to intensionalist elements

within natural languages, and his scathing criticisms of naturalism – his semantics does not reduce meaning to either use or to truth-functional, referential approaches – produced a trajectory of work that has been crucially important within linguistic semantics. He and Fodor proposed the first semantic theory in the framework of generative grammar: Starting with the semantic component of primitive lexical items, they showed that the meaning of longer expressions could be generated through application of recursive projection rules. Jackendoff’s “conceptual structure” approach also accepts this principle of compositionality and identifies an expression’s meaning with the mental representation of its content, but his semantics analyzes verbs and sentences in terms of the notion of abstract location and movement.

Religion

A central semantic problem arises in all religious traditions: What do religious and theological expressions *mean*? In the sixth century, Pseudo-Dionysius articulated the problem of how human language oriented to the finite can conceptualize and speak of the infinite:

Nor can any words come up to the inexpressible Good, this One, this Source of all unity, this supra-existent Being. Mind beyond mind, word beyond speech, it is gathered up by no discourse, by no intuition, by no name. (*On Divine Names*, 49–50)

Allegiance to this Dionysian-inspired apophatic tradition is found in varying degrees in most medieval theologians. Anselm’s unconceptualizable “that which none greater can be thought” and Aquinas’ analogical predication are two examples. Famously, the latter held that when referring to God, language is neither simply univocal (same sense) nor equivocal (different sense), but analogical: While the sense of the earthly term or predicate is stretched, it nonetheless remains applicable to the divine.

By the eighteenth century, trust in the apophatic approach had given way to suspicion. Hume suggested that because propositions in which “God” appears cannot be built up from propositions analyzable into simple ideas correlated to simple impressions, the propositions lack

meaning. Hume's insight clearly fueled twentieth-century concerns about religious language. Ayer famously denied truth-conditional semantics to religious and theological language entirely, asserting that all synthetic propositions not reducible to statements of sense experience are nonsense. Flew pointed out that because the believer's utterance, "God loves his children," is consistent with any way that the world might have gone, it is not falsifiable and thus meaningless.

Responses to this challenge were twofold: Some argued that the positivist theory of meaning was incorrect; others argued that religious language did connect empirically to the world by providing a label for particular empirically discernible patterns or a framework for explaining experience. Braithwaite argued that religious language communicates parables and stories that stimulate moral conduct, while Hare claimed that religious assertions merely state nonfalsifiable frames of reference ("bliks") that express evidentiary standards. Other accounts of religious and theological language include expressivist views in which religious language merely expresses human existential states and orientations, and metaphorical views where language functions nonliterally but sometimes referentially.

An interesting semantic issue concerns the putative reference of "God." Does "God" refer to a "rigid designator," the same individual in all possible worlds regardless of how language refers to it (Kripke), or does it denote a "world line," an individual that winds through possible worlds according to its identification within various intensional contexts (Hintikka)? The question is important religiously because it concerns the priority of semantics over both metaphysics and epistemology in religious contexts: Believers seemingly succeed in referring to God even in the absence of both metaphysical and epistemological accounts of the divine.

Characteristics

Important for understanding the significance of semantics is the "linguistic turn" of the last

century. While much of the history of philosophy has focused upon the object (world), the Enlightenment ushered in a preoccupation with the subject (self), the epistemic agent whose investigation was deemed necessary for knowing the world. Much on nineteenth-century philosophy continued in this subjective spirit by stripping meaning out of the world and locating it in "the head" (psychologism). Twentieth-century philosophy, however, made the "linguistic turn," arguing that meaning resided neither primarily in things nor in the head, but rather in language. This approach implicitly made semantics foundational for all reflection about the self and its relationship to the world.

Relevance to Science and Religion

The question of the semantics of religious/theological and scientific language is logically prior to relating these languages to each another. Consider the expressions "God created the heavens and earth" and "the universe resulted from the Big Bang." How are they locatable with respect to each other? Do particular statements in the sciences entail statements in religion or theology, or vice versa? Is there a statement entailed by one that conflicts with a statement entailed by the other? Crucial here is the question of how the terms and concepts of each discipline acquire and sustain meaning.

We can distinguish semantic atomistic, semantic molecularistic, and semantic holistic approaches. While the first claims that the meaning of a representation (term, concept, etc.) is that to which it applies, and the second that the meaning is determined by its relationship to other (but not all) expressions, semantic holism holds that the meaning of a representation is determined by its relationship to all other representations within the system. Accordingly, a linguistic statement has meaning only within the context of a language, a scientific hypothesis has meaning only in the context of a theory, and a concept has meaning only within the context of a belief system.

Obviously, if semantic holism is true, it becomes difficult to relate scientific and

theological statements, for an individual scientific statement s has meaning only within the context of an overarching scientific theory, and a religious statement r has meaning only within religious practice and reflection. But how is it possible to relate s and r without the religious person knowing enough scientific theory to understand s , and the scientist knowing enough theology to understand r ? In its most extreme form, semantic holism asserts *incommensurability* between religious/theological and scientific theory: There is no way to map meanings from one language into or onto the other. Fortunately for the religion/science discussion, claims of incommensurability are overstated, for the necessary condition for plotting the semantic difference of these putatively disparate languages is the existence of a common background language onto which the sentences of each can be mapped.

Sources of Authority

Philosophical semantics grounds its authority in logical analysis, and linguist semantics finds authority in empirical methods coupled with such rigorous analysis. Clearly, both make extensive use of logic and set theory, and one cannot enter the discussion deeply without competence in these areas. Crucial for the development of philosophical semantics in the twentieth century has been the work of Frege, Wittgenstein, Russell, Tarski, Quine, and Davidson. Within linguistic semantics, the work of Chomsky, Katz, Montague, and Jackendoff has been especially significant. Important journals in the field include *Linguistics and Philosophy*, *Natural Language Semantics*, *The Journal of Semantics*, *Mind and Language*, and *The Journal of Logic, Language, and Information*.

Ethical Principles

Semantics is guided by standards of academic excellence that apply to the empirical sciences and philosophy generally. There is no special

code of ethics that guides the work of the semanticist. Scholarly societies include *The Linguistic Society of America*, *The European Society for Logic, Language and Information*, and *Die Gesellschaft für Semantik*.

Key Values

Just as human beings are curious about nature and the causal laws at work within it, so are they concerned with meaning and the regularities and laws governing it. Semantics' key values are mathematical precision and rigor. An example of such precision and rigor is *model theory*, a method by which artificial languages are granted interpretations.

One begins by assigning meaning to sentences through a *boolean interpretation*. Such an interpretation β assigns either "true" [1] or "false" [0] to each letter in language L . The interpretation is a *function* that maps for each and every sentence in L some unique value (1 or 0). For any sentence letter in L , say θ , and a particular boolean interpretation β_1 , we can say that " θ is true for β_1 " or " β_1 of θ is true." Because L is "truth-functional" – the truth-value of compound sentences are a function of the truth-value of simple sentences comprising them as they are connected by the five standard logical operators of negation, disjunction, conjunction, conditional, and biconditional – giving a boolean interpretation to the simple declarative sentences gives truth-values to all compound sentences. We thus obtain a "boolean model of a set." If every sentence belonging to a set Δ of sentences in L is true for a boolean interpretation β , then β models Δ . Accordingly, β models all simple sentences assigned as true under its interpretation, and all compound sentences model truth-functionally derivable from those sentences: " β models Δ " if and only if $\forall s \in \Delta [\beta(s) = 1]$, or more succinctly " $\beta(\Delta) = 1$." If no boolean interpretation models Δ , then Δ is *unsatisfiable*. If some boolean interpretation β_1 models Δ , then Δ is *satisfiable*. If for every sentence $s \in L$, and any interpretation β_1 , if s is true for every β_1 , then s is a tautology:

Furthermore, if any boolean interpretation modeling Δ also models θ , then θ is a tautological consequence of Δ . Accordingly, if β models $\Box$ and $\Omega \subseteq \Box$, then β models Ω .

Things become more complicated with predicate logic. Allow f to be a function that assigns an element from nonempty domain D to each logical name in the calculus. An interpretation I is a function that assigns either 0 or 1 to each 0-ary relation letter, assigns to each 1-ary relation letter a subset of D , and assigns to each k -ary relation letter a k -ary relation among elements in D . An interpretation specifies the domain, and the denotation of each sentence letter ($1 \vee 0$), the denotation of a 1-ary letter (a set), and the denotation of a k -ary letter (a set of ordered k -tuples). The naming function f then assigns a unique element in D to the names in the language. Thus, for the set of all Americans D , if b is Bush, and $P = \{x \mid x \text{ is an American president}\}$, Pb is true because $b \in \{x \mid x \text{ is an American president}\}$. A “naming interpretation” consists in the ordered pair $\langle I, f \rangle$ which assigns definite meaning to any statement of the language. A sentence θ is true for an interpretation I if and only if, $\forall f \in \langle I, f \rangle$, $(\theta) = 1$. $\langle I, f \rangle$ is a model of $\Box$ if and only if $[\forall \theta \in \Box](\langle I, f \rangle (\theta) = 1)$, that is, it is a model for $\Box$ if and only if every sentence in $\Box$ is true. A set of sentences $\Box$ is *satisfiable* if and only if $\Box$ has a model, that is, that they are all true given a certain interpretation and naming function.

Interpretations of models can be further studied as algebraic groups. Accordingly, an interpretation maps from a language “domain” onto a range that is a structure. The elements in the range of the mapping are the elements of a structure. A structure S models a set of sentences Ω just in case the interpretation models Ω . When an interpretation models Ω , we say that M models Ω , or that M is a model of Ω . “Model” thus carries two meanings: (1) It is an interpretation for which a given sentence or set of sentences is true and (2) it is a structure. A “theory” is furthermore defined as an ordered triple $\langle L_t, \Omega_t, \text{Cns}_t \rangle$, where “ L_t ” is the language of the theory, “ Ω_t ” the axioms of the theory, and “ Cns_t ” the semantic consequences of Ω_t . We say that “ θ ” is an *assertion* of theory T just in case $\theta \in \text{Cns}_t$.

Conceptualization

Nature/World

Semantics does not reflect directly upon the meaning of nature and the world, but rather upon the meaning of linguistic expressions about nature and the world. Because semantics deals with language, it is crucially important for those disciplines claiming knowledge of nature and the world, and is thus central in understanding the nature of scientific theory.

Human Being

One way that semantics connects to the question of human being is in the relationship between semantics, linguistics, and psychology. If scientific semantics is a subset of linguistics, and linguistics – as many argue – is a subset of psychology, then the study of semantics must tell us something about ourselves. Moreover, if one is committed to mentalism, then it is clear that when humans learn about semantics, they are learning something about their own capacities for inner representation.

Life and Death

Semantics does not deal with questions of life and death but is concerned with any interpretation of the meaning of questions about life and death.

Reality

Semantics does not deal with metaphysical questions directly but is useful in disentangling them. This is particularly true when considering the phenomenon of reduction, the claim that the things talked about in one discourse (the reduced theory) *really are* things talked about in another discourse (the reducing theory). Examples of reductions in philosophy include *logicism* (reducing statements about numbers into statements of logic and set theory), *phenomenalism* (reducing statements about external macro-objects into statements of actual and possible experience), *logical behaviorism* (reducing statements about mental states into stimulus–response conditionals), *logical positivism* (reducing statements employing theoretical entities to ones referring only to observed

objects), and *naturalism* (reducing normative ethical statements to ones whose terms refer to natural properties only). All these philosophical reductions are semantic, for all use definitional equivalence statements (i.e., statements in the reduced theory just mean equivalent statements in the reducing theory).

Semantic reductions like these have been out of favor in philosophy since the 1950s, however, and have been replaced by theoretical reductions that understand the biconditionals connecting theoretical terms in the reducing and reduced theories as specifying coextensive property instantiations. While statements in the reduced theory *mean* something different than statements in the reducing theory, the reduced theory statements are true if and only if their corresponding reducing statements are true, e.g., the reduction of thermodynamics to statistical physics.

Reductions can also be found in theology and religion, though they are not often presented as such. For example, Kant semantically reduced talk of God to expressions about morality, while Schleiermacher reduced it to modifications of the feeling of absolute dependence. Marx, Freud, and Durkheim attempted theoretically to reduce religion to economics, psychology, and sociology, respectively.

A general philosophical question concerns the reduction of semantic content to some other domain. For instance, if one begins with materialist ontological commitments and regards the phenomenon of “meaning” as not conforming with these commitments, then one might want to eliminate, reduce, or somehow square claims of meaning with what one thinks there ultimately is, e.g., “naturalizing semantics.”

Knowledge

Epistemological questions arise in connection with semantic theories in a number of ways, the most obvious being the charge that semantics is not possible as a scientific theory. A powerful tradition of semantic skepticism associated with Wittgenstein claims that since linguistic expressions and utterances vary meaning from context to context and user to user, there is nothing

constant across the tokening of these expressions for a scientific semantic theory to be about. Another way semantic theory relates to knowledge is the verificationist criterion of meaning where knowing a statement’s meaning is knowing how to verify it. In this way, language-dependent epistemic norms become the subject matter of semantics.

Truth

Semantics is tied to truth within truth-conditional semantics. On this extensionalist view, the meaning of a declarative sentence is grounded in its truth conditions: To know what the sentence means is to know what the world would have to be like in order for the sentence to be true. Accordingly, semantics is concerned with *truth* for any syntactical language *L*. In order to understand this, we must distinguish an object language from a metalanguage.

Object language *L* is formed by specifying rules for the formation of proper formulas – so-called *well-formed formulas*. Here is an example:

$$\exists x \in D(Wx \ \& \ Px)$$

This states that there is some element of domain *D* that has *W* and *P*. The metalanguage *uses* words or symbols to *mention* the object language. For instance, one might say that the symbol “ $\exists x \in D$ ” specifies that there is at least one object within domain *D*, and “*Wx*” and “*Px*” state that this object has a particular property *W* and *P*, or alternately, that this object is simultaneously a member of the set of all objects having *W* and all objects having *P*. Assuming that the metalanguage *m* is used to mention the object language *L*, specific rules are given in *m* which specify necessary and sufficient truth conditions for each sentence in *L*. According to Tarski, the material criterion for truth of sentences in *L* is a statement like the following:

“ $\exists x \in D(Wx \ \& \ Px)$ ” is true in *L* if and only if there is someone who both walks and plants flowers.

The material condition for truth is given by that which follows “if and only if” in the locution, that is, “there is someone who both walks and

plants flowers” is an instance of the general material condition form:

... is true in L if and only if _____.

Tarski also specified a formal condition for L. Expressions of the form “is true in L” are precluded from themselves being in L. Semantic theory relates to truth when considering *truth in a model*. See “[Key Values](#)”.

Perception

An example of how semantics relates to perception is information-based theories that use the notion of covariancy to capture the perceptual information carried by the environment. An internal representation of a tokening of blue carries the information that something is blue in the environment. The symbol has the content of blue if and only if the symbol’s application covaries with the instantiations of blue in the environment. But a problem arises: Does the tokening of a rabbit covary with respect to rabbits, undetached rabbit parts, or temporal rabbit stages? Furthermore, the tokens of rabbit or blue must figure somehow in the percipient’s psychology: How does the internal tokening of a symbol relate to other internal states of the percipient?

Time

While there are many ways in which semantic theory might be linked to questions of time, the two are obviously joined in any intensionalist semantics that attempts to give a semantics for tensed verbs. The idea is that just as the meaning of a term can be understood as a function from possible worlds to an individual, so can the meaning of a tensed verb be understood as a function from moments of time to propositions true at those times.

Consciousness

The question of consciousness is tied to semantics loosely because if consciousness is understood as “aboutness,” then that which consciousness is about must have *meaning*. While phenomenology deals with content-meaning generally, semantics concerns the meaning of linguistic expressions and propositional attitudes. One might also argue that while

linguistic ability might not itself presuppose consciousness, the kind of linguistic analysis done in semantic theory clearly does because such analysis presupposes imagination and design capabilities.

Rationality/Reason

Semantics is a highly technical endeavor that demands disciplined observation, rigorous application of mathematical and logical resources, and philosophical sensitivity. Reason, however defined, is necessary for engaging in semantic analysis. Furthermore, the internal representation of semantic structures suggests a determinate contour to our structures of reasoning.

Mystery

With religious language, of course, the question of mystery arises in that words from mundane contexts are supposed to mean and refer to supramundane, divine entities, properties, relations, events, and states of affairs. Sensitivity to semantic issues can help clarify what is essentially mysterious and what is not.

Relevant Themes

To further significant dialogue between religion/theology and science, it is necessary to know the meaning of the statements of each and the expressions into which they can be decomposed. It is as easy for theologians not to understand the semantics of scientific theory as it is for scientists to misunderstand theological semantics. Sensitivity to semantic issues (and issues in the philosophy of language generally) is crucial for the future of these discussions.

[Semeiotic](#); [Semiology](#)

Description

Semiotics is the study of signs. That is, semiotics is concerned with such things as the processes of signification, representation, interpretation, and the nature of meaning. The field derives its name from the Greek *semeion*, meaning “sign.” The tradition of semiotics can be traced to antiquity, perhaps originating with the Greek physicians as the branch of medicine concerned with the interpretation of medical symptoms and signs. Plato and Aristotle were both interested in the nature of signs and the Stoics regarded the theory of signs as the basis of logic. Augustine (354–430) developed these philosophical approaches to semiotics in a Christian direction, regarding aspects of the natural world as signs of God’s will and activity in creation. Although an interest in what would now be called semiotics may be traced through medieval and Renaissance philosophy, the field only regained a sense of being a distinctive discipline in the wake of Locke’s (1632–1704) division of the sciences into natural philosophy, practical philosophy, and “semeiotica,” or “the doctrine of signs.” Locke predicted that semeiotic would “afford us another sort of Logick and Critick, than what we have hitherto been acquainted with” (*Essay Concerning Human Understanding* Book IV, Chapter XXI). The discipline(s) of semiotics as currently practiced, however, are largely traceable to the work of Swiss linguist Ferdinand de Saussure (1857–1913) and American scientist-philosopher Charles Sanders Peirce (1839–1914).

Self-Identification

Science

Saussure envisaged his “semiology” as “a science that studies the life of signs within society Semiology would show what constitutes signs, what laws govern them. Since the science does not yet exist, no one could say what it would be; but it has a right to existence, a place staked out in advance” (quoted in Nöth 1995, 57). Peirce, in contrast, regarded semiotics as a branch of philosophy rather than a “special science” (equivalent to, say, biology or physics). Nevertheless, Peirce thought philosophy itself should proceed by the method of science. He divided philosophy into (1) ► [phenomenology](#), (2) the normative sciences, and (3) ► [metaphysics](#), and the normative sciences were further subdivided into (a) aesthetics, (b) ► [ethics](#), and (c) ► [logic](#). Logic includes, or is constituted by, semiotics because all thought takes place in signs; logic “may be regarded as the science of the general laws of signs” (Peirce 1998, 260).

Religion

Semioticians would not understand their academic discipline as a religion. Semiotics is sometimes regarded as somewhat obscure and isolated from other academic disciplines (though its essence is, in fact, intrinsically interdisciplinary) with the result that some outside the field may regard it as a “religion” in a pejorative sense.

Characteristics

Semiotics is distinctive in studying that on which all other disciplines rely, namely, the possibility of representation, signification, and interpretation. In that sense, semiotics may be regarded as conceptually prior to, and necessary for, the practice of all other disciplines. Semiotics is therefore intrinsically interdisciplinary in nature, even though practitioners of other disciplines are often not explicitly aware of their reliance on the subject matter of semiotics.

Relevance to Science and Religion

The history of semiotics has many contacts with religion: witness, for example, the centrality of

the concept of “signs” in the Fourth Gospel, Augustine’s semiotic view of the created order, Aquinas’s semiotic account of the sacraments, and the relation between biblical studies and the origin of the discipline of hermeneutics. Given that neither science nor religion can function without using signs and representations of various kinds and given that the ultimate concerns of both would appear to be closely related to the view one takes of how signs work, it is perhaps surprising that the discipline of semiotics has not been more extensively drawn upon by the field of “science and religion” (See Robinson 2010 for an attempt to do so).

Sources of Authority

As noted above, Saussure understood his “semiology” as a branch of science and hence, presumably, would have expected it to proceed on the basis of empirical investigation rather than deference to any authority. Similarly, Peirce regarded emancipation from authority as essential to the whole enterprise of philosophy and science. Nevertheless, two fairly distinctive traditions of semiotics can be traced, respectively, to these founders of modern semiotics. In that sense, it may be helpful to regard Saussure and Peirce as “authorities” in relation to their respective traditions.

Saussure suggested that signs consist of two elements, the signifier (the “sound image,” the spoken word) and signified (the mental concept to which the sound image corresponds). He regarded these two aspects of the sign as related arbitrarily but inseparably – signifier and signified are like the back and the front of a piece of paper; one cannot be cut without affecting the other. A feature of Saussure’s dyadic concept of the sign is that it does not include any element relating to a real, external world. Saussure’s interest was in the relations between signs within a system. Hence, the label “structuralism” to describe the project that he initiated: the Saussurian tradition is interested in how systems of meaning hang together as a whole, rather than in how individual elements in the system connect with some non-semiotic reality.

Peirce, in contrast, proposed a triadic concept of the sign, according to which signs consist of a sign vehicle (sometimes simply referred to as the sign), an object, and an interpretant (the latter being the interpretive response of some agent, not necessarily a conscious interpretation). In his early semiotic theory, Peirce envisaged an endless progression of thought signs, each sign being interpreted by a further sign. This idea of unlimited semiosis is similar to Saussure's position in that it does not offer a clear account of how (if at all) signs connect with the world. Peirce later modified this view when he recognized the importance of "indexes": sign vehicles which are connected to their objects directly or causally (as when a weather vane indicates the direction of the wind). (Apart from indexes, Peirce proposed two other kinds of sign-object relations. Icons represent their objects by virtue of some resemblance; symbols are signs related to their objects by a rule or convention.) Furthermore, according to Peirce, not all interpretants need be thoughts: interpretive responses can also consist in actions (including, perhaps, very simple changes of state of an entity) or feelings.

The Saussurian and Peircean traditions have developed in ways that reflect these underlying differences. The Saussurian tradition has tended to remain anthropocentric. Its difficulty in giving an account of the connection between signs and reality tends to lead to a non-realist epistemology. For example, Michel Foucault claimed to identify a transition occurring in the seventeenth century when a previously triadic concept of the sign (stemming from the Stoics) was replaced by a dyadic concept. As Nöth puts it, "Thus a cleavage appears between the sign and its object. Since words no longer allow direct access to things, all that remains is representation, discourse, and criticism" (Nöth 1995, 305). Jacques Derrida took a step further, arguing that the idea of stable structures of meaning is problematic. According to Derrida, every sign in a system is marked by "traces" of every other sign. The system is characterized both by difference and "différance." Derrida coined the latter

term to allude to the alleged instability of systems of meaning: the meaning of any individual element is infinitely deferred and never fully consummated.

Peirce's semiotics, in contrast, lends itself (as Peirce intended) to a realist ► [epistemology](#). This is because Peirce's triadic concept of the sign includes an object. The object represented by the sign may be something quite abstract (such as a thought or concept) but can also be some actual thing in the (non-semiotic) world. Furthermore, again in contrast to Saussure's approach, Peirce's semiotics is not anthropocentric. Whereas the Saussurian tradition regards linguistics as the paradigm of all semiosis, for Peirce, language is one particular manifestation of more general semiotic processes. Consequently, Peircean semiotics has subsequently been able to expand to include the study of communication and signaling between nonhuman animals and organisms. Indeed, the field of "► [biosemiotics](#)" extends to the study of the role of representation and interpretation in fundamental biological systems such as the genetic "code" (e.g., Hoffmeyer 1996).

For the purposes of this entry, it will be helpful to emphasize the differences between the Peircean and Saussurian traditions in order to illustrate the potential consequences of different approaches to the concept of the sign. This strategy risks oversimplification, however, because it may overemphasize the degree of coherence within, and of separation between, each of the two traditions. Several major semioticians, including Roman Jakobson (1896–1982) and Umberto Eco (b. 1932), may be regarded as drawing on both the Peircean and Saussurian traditions.

Ethical Principles

Peirce regarded logic (of which he saw semiotics as a part) as the third of three "normative sciences." According to Peirce, aesthetics is the study of what is good in itself, ethics is the study of right control of conduct, and logic (including semiotics) is the "science" concerned with establishing right ways of reasoning. The

practices of the “special sciences” (physics, biology, etc.) were, in Peirce’s view, understood to be subject to the principles established by the three normative sciences.

Key Values

Peircean semiotics has, in general, retained closer connections with the natural sciences than has the more anthropocentric Saussurian tradition (see [Sources of Authority](#)). If Peircean semiotics tends to align itself with the values of the natural sciences (see [Ethical Principles](#)), then arguably the outworking of Saussure’s concept of the sign leads toward a different set of values, namely, the values of “suspicion” and “critique.” However, making such a distinction risks oversimplification, not least because the boundaries between the Peircean and Saussurian traditions are not always clear-cut (see [Sources of Authority](#)).

Conceptualization

Nature/World

Peirce once wrote that “all this universe is perfused with signs, if it is not composed exclusively of signs” (Peirce 1998, 394). In fact, Peirce’s philosophy is not consistently quite so “pansemiotic” in its vision as this statement may suggest. Nevertheless, Peircean semiotics at least regards everything in the world as having the potential to become a sign of something else. On the other hand, the Saussurian tradition, in keeping with its anthropocentrism and its lack of an account of the connection between signs and things, tends to be more agnostic about the nature of the world that is represented by semiotic systems.

Human Being

A particular contribution of semiotics to understanding the nature of humanity is to raise the possibility that what makes humans distinctive is our capacity (or the extent or specific form of our capacity) for using signs. This is reflected, for example, in Ernst Cassirer’s designation of

humans as the *animal symbolicum*. More recently, Terrence Deacon has proposed, from a Peircean perspective, an account of human evolution according to which we may be regarded as “the symbolic species” (Deacon 1997).

Life and Death

The field of biosemiotics, stemming from the Peircean school, regards semiotic processes as fundamental to life. Indeed, it has been suggested that the origin of semiosis is closely related to, and perhaps even defines, the origin of life. Although the origin of “coded” information in macromolecules such as deoxyribonucleic acid (DNA) is often regarded as central to the problem of the origin of life, the semiotic perspective suggests that a more general and fundamental issue may be the question of the simplest entity that would, in some minimal sense, be capable of interpreting its environment (Robinson and Southgate 2010).

Reality

As noted above ([Sources of Authority](#)), the Saussurian tradition tends toward a non-realist or antirealist view of the relation between signs and the world. Saussure described the non-semiotic world as “a vague, uncharted nebula” (quoted in Nöth 1995, 81). Peirce, in contrast, described himself as a “scholastic realist of a somewhat extreme stripe” (Peirce 1931–1935, 5.470).

Knowledge

Although the two main semiotic traditions differ in their attitudes to reality, they tend to share a commitment to epistemological non-foundationalism. That is, they do not seek any indubitable starting points for knowledge, either in reason (as did Descartes) or in sensory experience (as do philosophical Empiricists). As Peirce put it:

“But in truth, there is but one state of mind from which you can “set out,” namely, the very state of mind in which you actually find yourself at the time that you do “set out,” – a state in which you are laden with an immense mass of cognition already formed, of which you cannot

divest yourself if you would; and who knows whether, if you could, you would not have made all knowledge impossible to yourself?" (Peirce 1998, 336).

Peirce called his theory of inquiry "critical common-sensism" and regarded it as a development of the "common-sense" philosophies of eighteenth century Scottish thinkers such as Thomas Reid (1710-1796) and James Beattie (1735-1803).

Truth

Peirce conceived of "truth" in terms of the opinion that would be reached by the community of inquirers if investigation were to proceed well enough and long enough:

"The opinion which is fated to be ultimately agreed to by all who investigate, is what we mean by the truth, and the object represented in this opinion is the real. That is the way I would explain reality". (Peirce 1992, 139)

Peirce's notion of the final opinion, as originally formulated, is not entirely satisfactory. Peirce himself acknowledged that he might be asked what he would have to say "to all the minute facts of history, forgotten never to be recovered, to the lost books of the ancients, to the buried secrets" (Peirce 1992, 139). On Peirce's original view, these buried secrets and lost facts would not count as real even though they actually occurred. Conversely, it appears that were the community of inquirers to come to permanently hold an opinion that is at variance with the actual facts, then this opinion would, even though false, be held (by definition) to correspond to reality. Peirce's later formulations of the concept of truth avoid these problems by treating the idea of an ultimate convergence of opinion as a regulative ideal rather than as an inevitable historical occurrence. He therefore came to regard the existence of external reality as the ► [explanation](#) for observed convergences of opinion, rather than making the convergence of opinion constitutive of reality.

In the Saussurian tradition, the tendency toward agnosticism about the capacity for signs to represent a real non-semiotic world leads

to different kinds of question about truth. Questions of interpretative correctness relate more to the "text." Where previously (e.g., with Schleiermacher's biblical hermeneutics) the aim of interpretation was regarded as that of discovering the original intentions of the author, hermeneutics now tends to give priority to the interpreter, even to the extent of regarding the intentions of the author as irrelevant. Interpretation is always, according to this view, part of a "hermeneutic circle," a reciprocal relation consisting in "the interplay of the movement of tradition and of the movement of the interpreter" (Gadamer, quoted in Nöth 1995, 336).

Perception

A question semioticians might ask about perception is whether perceptions are pre-interpretive occurrences or whether they involve interpretation. Husserl (1859–1938) – whose term "phenomenology" was independently coined at around the same time by Peirce – took the former view. According to Husserl, the threshold of the origin of semiosis lies above, and depends on, a pre-semiotic intuition of the phenomena. Peirce, in contrast, regarded perception as much more closely related to, and perhaps inseparable from, interpretation.

Time

Semiotics does not have any unified approach to time, though it does grace the branch of semiotics devoted to how time is represented with the name "chronemics." The two main traditions of semiotics may be regarded as approaching their subject matter from different temporal perspectives. Thus, part of the originality of Saussure's project was to shift attention from the ("diachronic") evolution of languages to the ("synchronic") structural aspects of language at any particular time. Peirce, in contrast, was much interested in evolution and placed his semiotics within a speculative and highly original evolutionary cosmology.

Consciousness/Rationality/Reason

In a Saussurian perspective, the human capacity for using signs tends to be regarded as a product

of ► [consciousness](#), rationality, and reason. In contrast, Peircean semiotics regards consciousness, rationality, and reason as products of semiotic processes. As Peirce remarked, “just as we say that a body is in motion, and not that motion is in a body we ought to say that we are in thought, and not that thoughts are in us” (Peirce 1992, 42).

Mystery

Semiotics does not have any unified approach to mystery, though it has been suggested that “The model of the sign is the model of the sacred: a relation to the Absent, to the Other” (Cassirer et al., quoted in Nöth, p. 381).

Relevant Themes

Three themes may be picked out from the discipline of semiotics that appear particularly relevant to the field of “science and religion”:

1. An epistemological theme: the question of the relation between representation/interpretation and any reality external to such representation. Do religious/theological representations refer to something external to the mind or society that produces them, or are they to be understood in a non-realist sense as (merely) products of these minds/societies. Does religion/theology differ from science in this respect?
2. An anthropological theme: how are we to understand human religious practices and “symbols” (or, more strictly, “signs”) in the light of the discipline of semiotics? Do religious signs/symbols function in the same way (though with different “objects”) as representational practices in the sciences?
3. A theological theme: how do religions construe the relation between sign processes in nature and the existence and creative activity of God? The Fourth Gospel, echoing the first chapter of Genesis, speaks of God having created the world through the “Word”/Logos (John 1.1–3). Can traditional accounts of the role of the Logos in creation be revived or reframed in the light of contemporary semiotic

perspectives in such a way as to cohere with current scientific understandings of the world (cf. Robinson 2010)?

Sense-Datum Theory, The

Catharina Stenqvist¹ and Anne L. C. Runehov²

¹Centre for Theology and Religious Studies,
Lund University, Lund, Sweden

²Department of Systematic Theology,
Copenhagen University, Copenhagen,
Denmark

Briefly means that the perception is been given or sensed (which is in line with Alston's thinking). A distinction is made between the mental act of perceiving or sensing and the object of the perception or sensation. This theory is open for perceptions that may be illusory, because it treats all phenomenal properties as properties of the immediate object of experience. Hence, if an object is perceived as having a property that in reality it does not have, the theory says that some other object, as sense-datum, has this property. Simply put, the sense-datum theory holds that if somebody has a sensory experience, there is something of which this person is aware (Broad 1923; Moore 1910; Crane 2011). Objections to the theory are that the theory places itself between the experiencer and the experienced and therefore it does not solve the problem of how our senses perceive the world (See also the entry by Runehov on ► [Religious Experiences](#)).

Sensory Cortex

Neil Spurway

University of Glasgow, Glasgow, Scotland, UK

A region of the brain surface which mediates responses to sensory stimulation. Strictly, there are several sensory cortices, each responsive to one form of sensory input – visual, auditory, etc. – and in most cases more than one such area per sensory modality. As a stand-alone term, however, “sensory cortex” usually implies the primary somatosensory cortex, a large strip

extending across the center of the cerebral cortex from the fissure between the hemispheres to the temporal lobe of each side, and activated by mechanical, thermal, etc., stimulation of the skin and deeper regions on the opposite side of the body.

Description

Sex

Biological/anatomical diversity between male and female, determined by the chromosome structure possessed by every human being.

Biological Specification

Chromosomal framework and sexual differentiation. It is an indisputable fact that when a human being is born, its sex is determined by the male gamete. Then the information that guides the growth of the cells, the differentiation, and the structuring is all codified inside the chromosomes. The difference male/female is given by the presence or absence of the Y chromosome in the last pair, of the 46 chromosomes, of the human cells. The chromosomes that determine sex are defined as X and Y.

That human beings have 23 pairs of chromosomes, which include 22 autosomes and one pair of sex chromosomes, either XX or XY (the Y chromosome in spite of its small size contains more than 86 genes; the X chromosome contains about 200–300 genes).

During meiosis, the spermatocyte is divided to form the spermatozooids, the sex chromosomes split into two, the Y chromosome goes to a spermatozoid and the X chromosome goes to another. In this way, every spermatozoid is endowed with 22 chromosomes (called autosomes as they are not involved in determining sex) and with one X or one Y chromosome. Because the mature but not fertilized egg cell, for the process of chromosomal reduction, always contains 22 chromosomes and an X chromosome, when it is fertilized by a spermatozoid that contains an X chromosome, the zygote will have its 23 pairs of chromosomes, including an XX and will be a female; instead if the egg cell is fertilized by a spermatozoid that contains a Y chromosome, the zygote will have 23 pairs of chromosomes, including an XY and will be a male.

The presence of the Y chromosome, through what is called the Sry gene, gives the signal for the development of the male gonad, independently of the female sex chromosomes (X chromosome) present. The absence of the Y directs the development of the individual in a female sense. Therefore, at the moment of conception, the genetic sex, male or female, is determined in the last pair of chromosomes present in the zygote. If the last pair of chromosomes is XX, we will have a female individual; if it is XY,

a male will be born. Actually, even if the formula of the sex chromosomes is defined in the zygote, the earliest fertilized one-cell stage of development of the embryo, true sexual differentiation of the external genitals and reproductive organs occurs in the human embryo at the sixth week of pregnancy. The brain sexually differentiates as male or female in the third trimester of pregnancy (Jegalian and Lahn 2002).

Social Specification

In social life, sex is defined as an “independent variable” that might or might not influence attitude and behavior (Parsons 1991).

Despite numerous studies on the issue developed intimate behavior, in some social class, is still a taboo. After numerous studies, emerging from recent statements, in possession of social psychology with reference to the intimate behavior of individuals are: changes in the sexual expression and costumes, differences/similarities between male and female sexual behaviors, reactions to sexual impulses and to pornography (Jaspers 2007). The difference between sexual behaviors is determined also in relation to the action of the nervous system: specifically sexual behavior is under the control of the interaction that the neuronal and hormonal activities.

The hypothalamus (the nervous system structure situated in the brain stem and controls body temperature, thirst, and hunger, and regulates sleep and emotional activity), through a hematic feedback, controls the production of gonadotropic hormones by the pituitary gland, so it regulates certain aspects of reproductive and sexual behavior (Reese and Sanders 2007).

Gender Difference

The difference between male and female that is evident in the physiological sphere affects also the social-cultural sphere and therefore, we speak about gender difference. To be a female or a male is not just determined by purely physical factors but also by a series of behaviors that indicate the female or male status/role, as can be noticed not only in working contexts, but in social-religious ones as well (Guionnet and Neveu 2005).

Gender/Role

The gender is the first category that identifies an individual socially and therefore is at the base of the classifications and of the relations that have a social matrix. "Diversity" is a process that transforms the biological differences into social differences, thereby defining the man/woman representations. A role is a model that includes behavior, duty, responsibility connected to the female and male sex and is the object of social expectations (Delphy 1998).

The male or female role (excluding the obviousness of the biological evidence) derives from the result and the interactions of a series of social-cultural processes of the various public systems with a consequent complex of behavioral rules differently addressed to the individuals of the one and the other gender. H. Schelsky (1912–1984) states that these different rules tend to limit the natural inclinations of individuals producing social-cultural and economic tensions (Schelsky 1955). H. Popitz (1925–2002) follows Schelsky's footsteps. The scholar affirms that the holders of the gender roles are both the addressee and the beneficiary of the rules: In the first case, they are bound by the different rules of behavior according to the gender they belong to; in the second case, the rules do not only lay down the duties but also the rights and advantages of the corresponding addressees (Popitz 1967).

It is necessary to make a distinction between the gender role (masculine/feminine) and behavior and general behaviors. Being a male or a female is different from being a *vamp*, a *dandy*, a *macho*; or living with the conviction that a boy cannot cry or that women need to be constantly protected. Furthermore, in the gender roles, it is convenient to distinguish between *ascribed* roles and *acquired* roles. The ascribed role is of a natural, social order defined at birth. It is an ascribed role to be a man or a woman, young or old, free or enslaved, noble or plebeian. For every role, there are individual differences that regard both the interpretation and the realization of the role itself.

The acquired role is obtained during our lives through the activities and the performances of every single individual. It is an acquired role to

be a husband or a wife, a father or a mother, a pensioner or a student (Toscano 2006). The first scholar to introduce the distinction between ascribed role and acquired role is Ralph Linton (1893–1953). The scholar asserts that the gender roles were ascribed, unlike the professional roles that were instead acquired (Linton 1936). Today, especially in a society with a high rate of variability of the human species, the acquired roles prevail over the ascribed ones (Toscano 2006).

Division of the Social Roles in the Religious Sphere
Every religious perspective in all ages has given to women a subordinate and limited role. The monotheistic religions are exclusively male. In Christianity, God almighty is called "Father," and his representative on earth, Jesus Christ, is conceived as "Son." Woman, because of original sin, is considered by many Christians to be the cause of the first evil. It is not her but "the devil," the Lord of hell. This male supremacy needs to be distinguished between the Old and the New Testament: In the case of the Old Testament, the Genesis says that God created man and woman in his own image and likeness.

For this reason, the two genders have equal dignity and equal nature; but from the moment that God created the male (that is man) first, the first gender is the masculine one and the female created from man's rib has a feminine gender that is second. In terms of time and function, man results to be superior to woman and his characteristics of noble, honorable, strong sex become the universal standard of the behavior in accordance to the role. Instead the woman embodies the deviated role: the seductress, the sinner, the "weak sex," the derived gender.

This deviated profile is extended also to the female body, through biological constructions, elevated to anthropological constant. In contrast to the "pure" man, the woman is considered because of menstruation "impure" and for this reason is bound by a series of prohibitions (Biale 1992).

The Muslim religion, like the Christian one ever since ancient times, has considered women greatly inferior to men. It is sufficient to consult the *Koran* to notice the sharp supremacy of man

over woman starting from everyday life with the obligation to remain silent and to keep the head and the face covered. *Veil = HIJAB*: Arabic word whose root is *hjb*. The term means “to hide the eyes, conceal,” and indicates “any veil in front of one being or object to hide it from view or to isolate it.” In the Sura An-Nūr (The Light) it is said: «And tell the believing women to reduce [some] of their vision and guard their private parts and not expose their adornment except that which [necessarily] appears thereof» (*Koran*, Sura XXIV, 31).

In the first case, the religious man has assured himself the exclusive right of the exegesis and of the preaching and even of the top positions in the religious institutions. The imposition to keep the face and/or the head covered still is in force in the Islamic world: The obligation to wear a veil has become a universally “recognized” symbol of the subordinate role of women while for men to go bare-headed and with a beard symbolizes their direct contact with God. In the Jewish culture, it is above all the woman’s role of “mother” that is emphasized (Ahmed 1993).

The assumption of the maternal role in this case seems to be a makeshift given to women in order to take them away from the negative female roles but actually there are other female roles inspired by chastity, virginity that have permitted women to deny their female sexuality and to transform themselves “spiritually into men.” It is interesting to notice that in almost all the religions, the exegetic and doctrinal aspect of religion is male, while the procedures and the realization of the precepts are female (Schelsky 1955).

The current orientation, above all in Christianity, wants a new social role of women to stand out that is not considered in a subordinate dimension anymore, but equal to the specific role carried out by man. In short, in the sphere of Catholicism, even the most accredited positions in matter from the recent popes are directed toward the confirmation of the peculiarity of the mission assigned to man (such as the presbyterate), but they also exalt the peculiarity of the female mission inside the church (Levitt 1995).

Many religions emphasize the need to respect differences of gender according to their biological sex, male or female.

Sex Drive, The

Roland Karo
University of Tartu, Tartu, Estonia

A motivatory complex aimed at seeking copulation. May be thought of as one of the three fundamental mating drives: (1) the sex drive motivates an individual to seek copulation with a *range* of partners and is mediated by testosterone and estrogens; (2) courtship attraction motivates an individual to prefer a *particular* partner and is mediated via pheromones, dopamine, norepinephrine, and serotonin; (3) partner attachment motivates an individual to *remain together* with a particular partner long enough to allow for sufficient parental care and is mediated via oxytocin and vasopressin (Fisher, H. (2004). *Why We Love: The Nature and Chemistry of Romantic Love*. NY: Henry Holt & Co.).

Description

Simulation theory is a theory in philosophy and psychology on the way in which we understand others, particularly in common sense psychological (“folk psychological”) explanation and prediction of action. The central claim is that understanding another person is a matter of re-creating or copying the other’s beliefs, desires, and other mental states in one’s own mind. The interpreter thus functions as a model of the target system, the other person, in a way similar to that in which an airplane model simulates the reactions of a real airplane. In some cases, the interpreter voluntarily and consciously imagines herself being in the other’s situation and seeing it from her perspective, having her background beliefs, desires, evidence, and so on. However, following the discovery of so-called mirror neurons (see Gallese and Goldman 1998), the recent debate has brought more primitive and automatic forms of mental replication into focus, which do not necessarily require “putting oneself in the other’s shoes”. (See below on high-level and low-level simulation.)

Besides “simulation” or “mental simulation,” participants in the debate have used the terms “replication” (Heal 2003, pp. 11–27), “co-cognition” (Heal 2003, pp. 91–114), “projection,” “empathy” (Stueber 2006), “empathetic understanding,” and synonyms and cognates of the last-mentioned terms, such as “re-enactment of thought” and the German words *Verstehen*

(understanding), *Nacherleben* (re-experiencing), *Einfühlen* (empathy), and *Hineinversetzen* (transposition; Stueber 2006, p. 11). “Simulation” is the standard term in philosophy of mind and “empathy” in the philosophy and methodology of the humanities and social sciences (Stueber 2006; Davies and Stone 1995a, b; Kögler and Stueber 2000). In psychology, both terms are used (Harris 2000; Håkansson 2003). However, while “simulation” refers specifically to the understanding of others (“mind-reading” or “mentalizing”), “empathy” can also signify the sharing of others’ emotions, and the concern or benevolence for others, sometimes also referred to as sympathy. Some authors distinguish simulation and empathy as separate steps in a mental process where the interpreter first reads the other’s mind and then shares her emotions (Ravenscroft 1998), and some make even finer conceptual distinctions (for example, (Goldie 1999) conceptually separates simulation from understanding, emotional contagion, empathy, imagining oneself being in another’s shoes, and sympathy). Others use “empathy” for the whole process (Stueber 2006).

Simulation and empathy are thus to some extent interchangeable terms, and the two theory traditions overlap. However, simulation theory is a strand in analytical philosophy of the last few decades, while empathy theory has roots in German nineteenth and twentieth century hermeneutics and aesthetics (Stueber 2006, pp. 5–19; Kögler and Stueber 2000). Unlike empathy theory, simulation theory is exclusively concerned with the phenomenon of understanding and interpretation of others (and to some degree oneself). Moreover, simulation theorists have investigated understanding as a topic in philosophy of mind, but have had less to say on philosophy and methodology of the human sciences and moral philosophy, which are central topics in empathy theory (Davies and Stone 1995a, b; Kögler and Stueber 2000). An exception here is Karsten R. Stueber, who discusses both philosophy of mind and philosophy of science, using preferably the term “empathy” but referring mostly to theorists in the simulation tradition, thus connecting the two traditions (Stueber 2006).

Some prominent simulation theorists, mentioned in alphabetical order, are Alvin I. Goldman, Robert M. Gordon, Jane Heal, and Karsten Stueber. Historically, the theory originates in two articles from 1986 by Gordon (Davies and Stone 1995a, pp. 60–73), who introduced the term “simulation,” and Heal (2003, pp. 11–27). However, the prehistory goes as long back as the theory of empathetic understanding. Thus, it includes R.G. Collingwood’s theory of re-enactment of thoughts as the method of history, Wilhelm Dilthey’s theory of understanding in the human sciences, and, at least according to some interpretations, David Hume’s and Adam Smith’s theories of sympathy (on the history of empathy theory, see (Stueber 2006; Kögler and Stueber 2000; Nilsson 2003)). In analytical philosophy, W.V.O. Quine, Robert Nozick, and Hilary Putnam have defended similar ideas using other terms.

One person may simulate another physiologically, for example, by ingesting a drug and predicting that it will have the same effect on the other as it has on herself (Heal 2003, p. 14). In mental simulation, the interpreter exposes herself to the same situation as the other, or imagines herself being so exposed, and assumes that the other will respond by forming the same beliefs, desires, and volitional states as the interpreter does herself. For instance, I may venture to explain Hamlet’s decision to revenge his father by imagining myself being in Hamlet’s place, realizing that my father has been murdered, reacting emotionally to this insight, going through the alternative courses of action, reaching a decision, and finally inferring the motives for Hamlet’s actions by assuming that he was motivated by the same reasons. To understand another’s thoughts on some subject matter, I thus think through the same subject matter myself, and assume that the other is similar enough to follow the same lines of reasoning as I do. The simulation account seems to offer an explanation of the fact that, in common sense thinking, we are often able to predict and explain the actions of others without seeming to know anything like a general psychological or brain physiological theory of their mental functions.

Simulation theory is opposed to so-called *theory theory*, according to which we do understand others precisely by employing a general theory of mind, a set of psychological or other theoretical assumptions by which we can infer the mental states of others from their observable behavior, and explain and predict their behavior from their assumed beliefs and desires (see Davies and Stone 1995a, b; Goldman 2006). On this analysis, the fact that we are often unable to account for our theoretical assumptions shows only that we know them tacitly rather than explicitly. Hence, theory theory takes folk psychology to employ essentially the same general methods or patterns of reasoning as common sense (“folk”) physics. By contrast, simulation theorists see a fundamental difference between the understanding of others and the understanding of nature. With regard to the last-mentioned issue, the debate repeats, or continues, the earlier controversy between that which is sometimes called positivism and hermeneutics, or methodological monism and dualism about the human sciences (Stueber 2006; Kögler and Stueber 2000).

Goldman has also opposed the idea of simulation to the *rationality approach* in interpretation theory, represented by Donald Davidson and Daniel Dennett, among others (Goldman 2006, pp. 4, 23–24, 53–68). According to this understanding or version of the simulation theory, the interpreter re-creates the other’s mental processes without assessing them with regard to their rationality. Hence, the same process of simulation is applied to irrational and rational thought and behavior. By contrast, Heal and Stueber argue that an interpreter who simulates another person ascribes to her the beliefs and desires which, according to the interpreter’s own standards, the other has reasons to hold in the circumstances (Heal 2003, pp. 6–7, 131–150, 225–249; Stueber 2006, pp. 65–97; rationality is here understood in a minimal sense of being responsive to reasons, rather than as the fulfilling of strict requirements of logical coherence and completeness, and Heal restricts herself to what below is called high-level simulation). Thus understood, simulation theory is a form of rationality theory, or overlaps with it.

It can be noted here that W.V.O. Quine, when laying the foundations for the rationality approach, regarded the “projecting” of one’s own logic and language on the other as integral to radical translation (Quine (1960), p. 58, see also Quine’s his analysis of indirect quotation, Quine (1960), p. 219).

It is relatively uncontroversial to say that one person can replicate another’s mental reactions in situations where both are literally in the same circumstances, or very similar ones, and have similar background beliefs and values (Stich and Nichols 1997, pp. 300–302). Gordon gives the example of someone who is hiking and sees a fellow hiker suddenly stop, turn around, and walk quickly in the opposite direction. Asking himself what happened, he looks ahead and sees a grizzly bear further along the path. Seeing this makes him at once experience the same feeling of fear as the other and understand the reason for the other’s behavior (Davies and Stone 1995a, p. 102). Simulation of this type has been called *total projection* (Davies and Stone 1995a, pp. 102–105) and *actual-situation-simulation* (Stich and Nichols 1997, p. 302).

If the other’s beliefs, values, or external circumstances are very different from the interpreter’s, as in many cases of historical interpretation and interpretation of people from other cultures, then simulation becomes more complicated and theoretically problematic. In principle, one could separate four categories of interpretive situations, from the simplest in which interpreter and other share both external circumstances and perspective (point of view, worldview) via the more complex in which they share perspective but not circumstances, and vice versa, to the most complex and demanding, in which they share neither circumstances nor perspective. Simulation in the last type of situation has been called *pretense-driven-off-line-simulation* (Stich and Nichols 1997, p. 303). For reasons explained below, this choice of term is controversial, however.

A further distinction can be drawn between what Goldman calls *low-level* and *high-level simulation* (Goldman 2006, p. 113, 147), and Stueber *basic* and *re-enactive empathy*

(Stueber 2006, pp. 145–147, 151–152). Low-level simulation replicates relatively simple mental states, some of which lack propositional content, such as fear and disgust. It enables us to recognize simple emotions in others by immediate observation of their behavior – for instance, I realize that another is afraid by seeing her facial expression. Such simulation comes as a relatively automatic response, and largely operates below the level of consciousness. It seems closely connected to the phenomenon of emotional, cognitive, and motor contagion (mimicry, imitation) – which, for instance, invokes a feeling of joy in someone who sees expressions of joy in another, or makes someone jump when seeing another jump. There is evidence that low-level simulation depends on so-called mirror neurons, which are activated both during the execution of an action (grasping an object, for instance) and during observation of the same action being performed by others (Goldman 2006, pp. 113, 132–144). The interpretation of this evidence has been disputed, however (Gallagher 2007; Jacob 2008; Goldman 2009).

High-level simulation, by contrast, replicates more complex mental states, such as propositional attitudes, and is generally more voluntary and more accessible to consciousness than low-level simulation (Goldman 2006, p. 147). This is the type of simulation of which it seems appropriate to say that the interpreter imagines herself “being in the other’s shoes.” The nature of such simulation has been a topic of debate among simulation theorists. The two main positions which have emerged can be referred to as the *off-line simulation* view and the *imaginative identification* or co-cognition view respectively.

According to the off-line simulation approach, represented by Goldman and assumed by most theory theorist critics, high-level simulation is essentially a form of inference by analogy (which is not to say that it necessarily depends on all Cartesian notions associated with that idea). Thus, the interpreter simulates the other by imagining herself being in the other’s situation, introspectively observing the resulting goings-on in her own mind, assuming that the

other is sufficiently similar to herself to react in the same way to the situation, and finally attributing her own mental processes and states, or something very similar, to the other. In order to compensate for differences in background beliefs and values between herself and the other, the interpreter puts her cognitive apparatus into an “off-line” mode, where it does not receive its ordinary input or deliver its ordinary output. For the purpose of simulation, she introduces into her mind “pretend” beliefs and desires which match those of the other, suspends (or “quarantines”) beliefs and desires of her own which the other does not share, and disconnects her action motivating mental functions from her motor system so that she does not act on her pretend-beliefs and pretend-desires (Goldman 2006, pp. 28–30; Stich and Nichols 1997). For instance, a social anthropologist studying the Azande tribe attunes her own mind to that of the Azande by pretend-believing in magic, witches, oracles, and so on, without of course for that matter taking active part in Zande customs and rituals. (If there exist no relevant differences in perspective between interpreter and other, the interpreter may simply apply her ordinary ways of thinking “on-line.”) According to this view, the interpreter in simulation acts as a relatively detached observer of her own and the other’s mental states and processes (see Stueber 2006, p. 122).

Some of the central ideas in the conception of high-level or re-enactive simulation as imaginative identification are aptly summarized in the title of one of Gordon’s articles, “Simulation without introspection or inference from me to you” (Davies and Stone 1995b, pp. 53–67). According to this version of the theory, represented by Gordon, Heal, and Stueber, the interpreter’s focus of attention is not on the mind of either herself or the other, but rather on the world as perceived from the perspective of the other (Heal 2003, pp. 91–114; Stueber 2006, pp. 151–171; Davies and Stone 1995b, pp. 60–63). To simulate the other, the interpreter re-centers her ego-centric map of the world by shifting the reference of her indexical concepts to match the other’s, and simply imagines the world being the way it appears for the other – containing

witches and oracles, for instance. In doing this, the interpreter does not need to observe or consciously regulate her own mental functions. It is sufficient that she employs the ordinary human capability to imagine and hypothetically consider counterfactual states of affairs. Since the interpreter thus primarily looks at the world rather than at the other subject, simulation does not essentially involve introspection and inference by analogy from one's own mental states and processes to those of the other – although it can be argued, as Goldman, Stueber, and Heal have done, that the validity of simulation nevertheless depends on the minimal theoretical presupposition that the interpreter and the other are sufficiently similar in relevant respects. According to the imaginative identification view, the interpreter thus adopts a relatively engaged stance toward the other's mental goings-on, acting more as an active participant in the other's ways of thinking than as a detached observer of them. (Heal prefers the term "co-cognition" to "simulation" because the former suggests a more engaged and the latter a more detached mode of thinking, but despite this uses "simulation" to cover both off-line simulation and co-cognition; (Heal 2003, p. 92).)

Thus understood, the imaginative identification and off-line simulation views are conflicting interpretations of the nature of high-level simulation (re-enactive empathy). If otherwise construed, however, the two views are not necessarily contradictory. According to Heal, the co-cognition or imaginative identification view is an *a priori* analysis of the personal, or phenomenological, level of simulation, while the off-line simulation view is best thought of as an empirical hypothesis on the underlying sub-personal psychological or biological mechanisms (Heal 2003, pp. 108–111). What happens in the brain of an interpreter when he re-enacts the thoughts of others may well be that the decision making system is disconnected from the motor system, and so on, although the interpreter will normally be unaware of any such fact. If so, there is no real conflict between the two views. However, it is the imaginative identification or co-cognition view which primarily constitutes

an alternative to the theory theoretical analysis of our capacity to understand others.

This connects to a further issue of debate among simulation theorists, namely, whether the theory is empirical or *a priori*. Goldman is probably the strongest proponent of the view that it is an empirical and more precisely psychological and neuroscientific hypothesis, to be confirmed or falsified by empirical data like any other such hypothesis (Goldman 2006, p. 20). Heal takes the opposite stance, arguing that the ability to think about others' thoughts and the ability to think about the subject matter of those thoughts are non-contingently connected in the way postulated by simulation theory (Heal 1994, p. 141).

The arguments for simulation theory are both empirical and of a more traditional philosophical kind. In common sense thinking and interpretive sciences, we seem capable of understanding others without knowing anything like a general theory of their minds, at least not explicitly (Davies and Stone 1995a, pp. 60–73), and something like simulation, or empathy, seems to perform an epistemic function in such understanding, as suggested by everyday language expressions such as "I would have done the same if I were you" or "Imagine being in my shoes."

Although theory theory is probably the dominant view among psychologists, certain findings in empirical psychology and neuroscience fit well with simulation theory, among them the relatively recent discovery of mirror neurons, which has already been mentioned. Studies on autistic children have shown them to be deficient not only in their capacity to understand and relate socially to others, but also in their abilities to see things from other people's perspectives, participate in pretend play, imagine counterfactual possible worlds, and react emotionally to such worlds – precisely what one would expect if these two sets of abilities were connected in the ways simulation theorists claim. The interpretation of these data has been contested, however, and other empirical findings seem to fit better with theory theory than with the simulation view (Stueber 2006, p. 103, 116, 118; Goldman 2006, pp. 134–144, 200–206; Goldman 2009).

Heal and Stueber among others have pointed to cognitive economy as an argument for simulation (Heal 2003, pp. 50–59; Stueber 2006, pp. 154–158; Ravenscroft 1998, pp. 174–177). I simulate another's thoughts on a given subject matter by using my own capacities for thinking about the same subject matter, and the motives for her actions by using my own abilities to consider alternative courses of action, weighing reasons for and against, and so on. Therefore, little more is required for understanding and interpreting others than the affective, cognitive, and conative capacities that I already employ for other purposes. According to theory theory, by contrast, I need a complicated theory of the laws or regularities governing other people's thought and behavior. Heal even argues that such a theory would have to be orders of magnitude more complicated than common sense physics or any other theory, because it would have to take account of the many different worldviews which people have, with all their complexities, and the respective consequences of these worldviews and the differences between them for behavior in indefinitely many possible circumstances (Heal 2003, p. 58). However, cognitive economy can also be an argument for the methodological monism of theory theory against the dualism of simulation theory, since applying the same kind of methods to both nature and people is in at least some respect simpler than applying two different methods, or sets of methods (see Stueber 2006, p. 150).

An influential objection against simulation theory, originating from Carl Hempel and Daniel Dennett among others, may be referred to as the *anti-simulationist collapse argument* (Hempel 1965, p. 240; Dennett 1987, pp. 100–101). Using a plane model to simulate a real plane presupposes that the latter generally behaves like the former in the relevant ways. Otherwise the results of the simulation will not be relevant to predictions or explanations of the plane's reactions to high speed, etc. By analogy, mental simulation presupposes a sufficient degree of similarity between the interpreter and the other for them to react with the same mental output to the same input. This assumption can only

be justified by reference to general laws of psychology, which means that the supposed empathy-based explanation is in fact covertly theory-based. Hence, simulation is not really a distinct method of understanding, and the idea of mental simulation collapses into a version of the usual theory theoretical model of understanding. (This argument should be distinguished from the more general collapse argument, which questions the entire theory theory-simulation theory distinction and thus affects both positions equally; (Davies and Stone 2001).) A possible objection from proponents of the non-rationality approach is that the argument conflates the question how ascriptions of mental content are actually made with the question how they are justified; on the rationality approach, however, ascription is inseparable from justification.

In response to such objections, Goldman and Gordon in early articles defended a position that could be called externalism about simulation. According to epistemological externalism (of which Goldman is a proponent), it is sufficient to know something that one's belief on the matter has been produced through a reliable belief-forming process, such as visual observation in favorable conditions. Hence, it is not necessary that one is aware of reasons for one's belief, or for the assumption that the belief-forming process is reliable. In a similar vein, Goldman and Gordon have argued that successful simulation only requires the interpreter to be sufficiently and relevantly similar to the other, but not to have reasons for assuming this to be so (Davies and Stone 1995a, pp. 100–122; Davies and Stone 1995b, pp. 53–67, 74–99.).

A different response, perhaps most clearly stated by Arthur Ripstein, is that the interpreter can determine the degree of similarity between herself and the other by a kind of induction from particular cases. If the interpreter studies the other's statements and actions in a sufficiently wide variety of cases, and they consistently appear reasonable from the interpreter's own perspective, then she has reason to assume herself to be sufficiently attuned to the other, without thereby depending on a theory of the other's mind (Ripstein 1987; Bohlin 2009). That is, the

assumption of similarity is theoretical in the minimal sense that it is general and based on inductive reasons, but it is not a theory in the more demanding sense in which, according to theory theory, understanding of others depends on theory; it is an empirical surface generalization to the effect that the other in general reacts similarly in thought and action to the interpreter, not a theory of the inner structure or functions of the other's mind (see Stueber 2006, p. 180).

A third type of response has emerged in the later debate. The early theory theory-simulation theory debate was mostly dichotomous in the sense that understanding of others was assumed to be either entirely based on theory or else entirely based on simulation. More recently, hybrid positions have been developed, perhaps most fully by Goldman and Stueber (Stueber 2006; Goldman 2006). It has been maintained both that simulation can account for some but not all cases of understanding, and that even when we do simulate, the process of understanding combines simulation with theoretical inference.

For instance, Stueber argues that non-rational behavior requires other methods of explanation and prediction than simulation, or empathy, and that even central cases of simulation depend on theoretical assumptions. The argument for the last point is based on Stueber's division of the process of simulation into three phases, which he calls matching, simulation, and attribution. In the matching phase, the interpreter adjusts her own perspective to the other's, compensating for the relevant differences in background beliefs, evidence, and so on. In the simulation phase, the interpreter thinks through the subject matter at issue from the other's perspective. In the attribution phase, she ascribes the resulting cognitive, affective, and conative states to the other. Stueber argues that theoretical assumptions can play an essential role in both the matching and the attribution phase (Stueber 2006, pp. 120–121). When matching the minds of the Azande, for instance, it may be necessary for the interpreter to be aware of the fact that they generally believe in witchcraft and oracles, and it seems reasonable to say that any results of the

interpreter's attempts to see things from the Zande perspective will be valid only if, apart from the differences compensated for in the matching phase, the Azande are relevantly and sufficiently similar to the interpreter herself, or more generally to members of her culture, social group, and so on. However, such unsystematic contrastive generalizations about perspectives do not amount to anything like a fully developed theory of Zande mind, or the human mind in its Zande manifestations. To compensate for the lack of theoretical knowledge in this more demanding sense, the central simulation phase remains indispensable.

Simulators

Nathan Koenig
Interaction Lab, Computer Science Department,
University of Southern California, Los Angeles,
CA, USA

A simulator is a computer program designed to artificially recreate a robot and its environment. Many robotic simulators incorporate some form

of physics engine to simulate a robot's dynamics and kinematics, and a visualization system to provide sensor information to the robot and output for a human. Simulators aid in the development of new algorithms, in the debugging process, and facilitate rapid prototyping. They provide a safe environment in which to test theory and even write algorithms to control a robot in a hazardous environment.

Sin (Vice, Human Limits, Negativity)

Jay R. Feierman*

University of New Mexico, Corrales, NM, USA

Related Terms

[Evil](#); [Human limits](#); [Morality](#); [Punishment](#); [Vice](#)

Most current societies have lists of morally right and wrong actions that are often sanctioned or supported by a deity (God, superior being, force, or agency) capable of causing retribution (Lyman 1989). In societies with salvation religion, being out of favor with the deity may make one ineligible for salvation (Coward 2003). In some current societies, these immoral actions are restricted to overt behaviors. Sin may be viewed as reality, even embodied, next to the concept of evil; more frequently, it is an attribution, a way to qualify an act or behavior. In some societies, sin is against other people. In other societies, it is against the deity. Most societies have degrees of sin. All societies have ways or means of being relieved from sin (Ensor 1997). In some societies, sin is an act; in other societies, it is a state from which one has to be relieved to be in good standing or to be in a state of grace with a deity.

Sin is inexorably related to the concept of evil, which is that which is morally bad or wrong.

*Jay R. Feierman has retired from University of New Mexico

Virtually all sin is related to intentionality and the concept of free will. Because human beings may do things that are wrong or evil and because most concepts of deity attribute goodness and omnipotence to the deity, the concept of free will is also obligatorily related to the concepts of sin and evil, otherwise one would have to solve how a loving and good deity could allow evil human behaviors to occur. Many societies solve this problem by an evil deity or spirit who influences the free will of believers (Wright 2006).

Apart from setting and promulgating moral standards in a society, sin may have other functions. Whereas many sins are universal across societies, other sins are society specific. As such, they serve as religiously mediated in-group markers. They, along with the minimally counterintuitive and counterfactual beliefs that make up most religions, would help to bind the in-group together.

A vice is a habit or personal characteristic deemed immoral (Shklar 1985). Often, such behaviors are associated with such things as prostitution, sex with underaged children, illegal drugs, gambling, and even compulsive criminal activities. The degree to which some individuals are morally responsible for certain types of vice is difficult to determine, as certain individuals may be biologically predisposed to engage in behaviors that are nonnormative. The concept of criminal responsibility is not the same as moral culpability. Both crimes and what are considered morally objectionable behaviors have some degree of cultural and temporal relativity, as what may have been illegal or immoral at one point in time is not considered so in another point in time in the same society. Almost all human beings have moral vulnerabilities. Human beings differ in the degree to which they can conform their behavior to the legal and moral requirements of their society. As such, all human beings have their limits. The Native Americans understood this well with their often-quoted saying, "Do not judge another person unless you have walked a mile in their moccasins." Such an understanding can cause one to have compassion even for those who commit acts that are illegal and/or immoral.

Singularity

Robert M. Geraci

Associate Professor of Religious Studies,
Manhattan College, Riverdale, NY, USA

A term borrowed by popular robotics and AI theorists from astrophysics. Mathematically, singularity refers to a point at which the object cannot be defined. In pop robotics, it refers to the point at which exponential progress in computation produces social changes so enormous that they cannot be predicted from our present vantage. This is generally assumed to mean that machines will become extraordinarily intelligent, and human beings will merge with technology as cyborgs and, shortly thereafter, minds uploaded into machines.

Skinner Box

Jörg-Peter Ewert

Faculty of Natural Sciences, University of
Kassel, Schauenburg, Germany

A Skinner box is used in a laboratory setting to study associative learning in animals. The device was introduced by the behaviorist Burrhus F. Skinner around 1930. It can be utilized, for example, to test classical conditioning in a rat by associating a blue light with an enemy in each session, eventually causing the rat to be frightened not only by the enemy, but upon seeing the blue light. In an operant (instrumental) conditioning paradigm, for example, a rat's behavior upon pressing a lever is reinforced by food, eventually causing the rat to press the lever in order to get food.

Description

Sleep has been fascinating people for centuries. Besides dreams, sleep was considered to be the

brother of death in ancient Greece and has been taken as a state of “small death” until Berger in 1928 discovered the (electroencephalography) EEG and found that sleep has a different electrophysiological expression from the wake state (AASM 2005). In 1949, Moruzzi and Magoun showed that forebrain and cortical arousal/waking behavior is mediated by a set of ascending pathways that originate in the upper brainstem near the pons-midbrain junction called the “ascending reticular activating system” (Aserinski et al. 1953). When rapid eye movement (REM) sleep in the early 1950s was discovered by Aserinsky and Kleitman, sleep could be clearly described as two major different forms: non-REM and REM sleep, the first being found in different forms of sleep depth from stage non-REM 1–4 (Berger 1929, Daan et al. 1984). The analysis of the sleep microstructure was first standardized by Rechtschaffen and Kales in 1968; the latest revision by the American Academy of Sleep Medicine was performed in 2007 (Feinberg and March 1995, Hobson 1975). Further analysis of sleep microstructure established models such as the “two process model of sleep and wake” by S. Daan and A. Borbély in 1982, while in 1975, Hobson and McCarley discovered that the occurrence of non-REM and REM is based on the reciprocal discharge by two brainstem neuronal groups (Iber et al. 2007, Lu et al. 2006). More recent models of sleep-wake regulation have been established like the “flip-flop switch model” of orexin by Lu and Saper in 2006 which also shows the connections with the autonomous, the motor, the endocrine, and other systems (Manni et al. 2011).

In most western parts of the world, scientific activity in sleep research expanded fast and stirred the foundation of National Sleep Societies, which today are established scientific medical societies. As sleep medicine is not restricted to one faculty, it is the first “interdisciplinary society” also including nonmedical disciplines.

After classifying sleep disorders by establishing accepted methods, some very efficient therapeutic tools were developed. The most successful until today is the therapy for sleep apnea by applying “continuous positive

nasal airway pressure” (nCPAP) during nocturnal and diurnal sleep. Research was and still is revealing the impact of the different sleep stages on diurnal physiology, psychology, and cognition in all kind of medical and behavioral disorders. Sleep deprivation studies have led to insights into all kinds of accidents caused by sleepiness or other sequelae of disturbed sleep.

In the meantime, sleep has found its way into all major medical disciplines and is a source of new insights into pathophysiology, morbidity, and mortality. Sleep deprivation studies challenging cognitive processes have set a trigger to understanding the function of sleep for our mental capacities. Genetics have been of tremendous help identifying some initially “rare diseases” such as the “sleep phase advance syndrome” and the “sleep phase delay syndrome”; they are able to identify the chronotype of complete populations with their vulnerable wake and sleep times (Mayer et al. 2009).

Pharmacogenetics is gaining more and more importance as the number of medical products to induce healthy sleep and to prevent daytime sleepiness is increasing. Imaging is a further contributor to new insights into the molecular mechanisms of sleep and its relation to other systems.

Self-identification

Sleep medicine from its beginning on has been based on scientific methods. It is not a religion as it is based on the principles of scientific methods and not on belief. However, in ancient times and in traditional cultures, people would tell their dreams in the morning to keep in touch with their “inner spirits” (Moruzzi et al. 1949). Dreams have been interpreted in many mystified ways, they have been used extensively in literature as predictors of fate (i.e., Lady MacBeth by Shakespeare) or even a whole nation (the seven good and the seven bad years in ancient Egypt), and people lived up to them. These traditions of awareness of dream contents became a real psychoanalytic method with Sigmund Freud who focused on dreams as a feature of unconscious

wishes, while Hobson and McCarley stated REM-based dreams as a neural activity without any sense. Today, scientific methods show that a lot of equal brain regions are involved in REM dreaming, memory functions, and emotions or even the recall of emotions. Both the decrease of central regulatory control mechanisms and the dissociative tendencies of mental functions during REM may erase old affective patterns, allow the testing of new emotional behavior within a given situation and the subsequent selection, emphasizing these new learned affective patterns.

Characteristics

Since all findings clearly showed that sleep, respectively disturbed sleep, has a great impact on social life, productivity, and general health, sleep medicine is the first real interdisciplinary discipline which covers all fields of medicine including internal medicine, pneumology, cardiology, neurology, psychiatry, otorhinolaryngology, pediatrics, and others. Besides medical fields, it also includes nonmedical disciplines, that is, psychology, physiology, biology, physics, etc.

Relevance to Science and Religion

Dream research based on the scientific understanding of dreams has contributed very much to the understanding of “hallucinations,” “out of body experience,” and “appearances” (Palagini and Rosenlicht 2011). It has also shown that mankind is capable of commanding certain dream contents in a desired way (so-called lucid dreaming). The myth of “why we dream” and what the “individual meaning of dream contents” is has still to be fully analyzed (Rechtschaffen 1968, Toh et al. 2001).

Sources of Authority

The sources of sleep medicine are international classifications, guidelines, and recommendations

(see references) as well as established scientific procedures like PSG, first standardized by Rechtschaffen and Kales in 1968 and revised by the American Academy of Sleep Medicine was performed in 2007. Until today, the most important method to score sleep is the polysomnography which has 2–4 channels to record eye movements, 1–3 channels to record chin muscle activity, 3–8 channels to record scalp electroencephalogram, 1 channel for ECG, nasal airflow, thoracic and abdominal excursion, noninvasive oxygen saturation, and 1–2 channels (or more if needed) to record tibial anterior muscle activity. To classify disorders as parasomnias videometry is necessary to assess the behavioral phenotype.

These standardized methods helped to identify sleep disorders, which led to the first International Classification of Sleep Disorders in 1979 which in the meantime comprise more than 88 different disorders and which was revised in 2005 (Vogel 1960).

Ethical Principles

As for every medical subdiscipline, the ethical guidelines are the “Hippocratic Oath” and the “International Declaration of Helsinki.”

Key Values

The key values are diagnosis and therapy of sleep disorder worldwide. Specific health care activities focus on the teaching of the need for sufficient sleep in the general population.

Conceptualization

For all the items listed, the International Sleep Societies have given no general definitions.

Relevant Themes

Themes regarding the topic “Science and Religion” could be manifold. They could include time

management for religious services (i.e., to make the attendants more attentive), analyzing the scientific background of “appearances” occurring from sleep.

Social Construction in Psychology

Kenneth J. Gergen

Department of Psychology, Swarthmore College,
Swarthmore, PA, USA

Related Terms

[Constructionism](#); [Constructivism](#); [Social constructivism](#)

Description

The phrase, *social construction*, typically refers to a tradition of scholarship that traces the origin of knowledge, meaning, or understanding to human relationships. The term *constructivism* is sometimes used interchangeably, but much scholarship associated with constructivism views processes inherent in the individual mind, as opposed to human relationships, as the origin of people's constructions of the world. Social constructionism gained its initial prominence as a metatheory. It provided an account of all claims to knowledge, reason, and value – in science, religion, and elsewhere. On this level, it has served as a major alternative to empiricism. However, unlike empiricism, constructionists make no claims to the truth or ultimate rationality of constructionism itself. In this sense, constructionism may be viewed as a nonfoundational foundation.

However, constructionist ideas have also been used for purposes of substantive critique, description, and explanation of various social processes. At this level, constructionist ideas also give rise to new research practices, especially those considered qualitative. Constructionist ideas inform inquiry across the social sciences and humanities. They play a specially important role in narrative inquiry, discourse analysis, rhetorical studies, ethnography, cultural studies, conversation analysis, interpersonal communication, feminist inquiry, neocolonialist inquiry, organizational studies, the social studies of science, the history of science, and critical studies, among others.

Constructionism offers a major alternative to individualist and biological accounts of human behavior. Constructionist ideas also inform the development of numerous practices in society, especially those centering on dialogue, personal and social transformation, organizational development, and peace building. Many view constructionist ideas as the backbone of postmodern therapeutic practices. For further discussions of constructionist inquiry and applications, see Gergen (2004, 2009), Holstein and Gubrium (2008), Lock and Strong (2010).

Root Assumptions in Social Construction

Although one may trace certain roots of social constructionism to Vico, Nietzsche, and Dewey, scholars often view Berger and Luckmann's *The Social Construction of Reality* as the landmark volume (Berger and Luckmann 1967). Yet, because of its lodgment in social phenomenology, this work has largely been eclipsed by more recent scholarly developments. One may locate the primary stimulants to the more recent development of social constructionist thought in at least three, quite independent movements. In effect, the convergence of these movements provides the basis for social constructionist inquiry today.

The first movement may be viewed as *critical* and refers to the mounting ideological critique of all authoritative accounts of the world, including those of empirical science. Such critique can be traced at least to the Frankfurt School, but today is more fully embodied in the work of Foucault (Foucault 1980) and associated movements within feminist, black, gay and lesbian, and antipsychiatry enclaves. The second significant movement, the *literary/rhetorical*, originates in the fields of literary theory and rhetorical study. Poststructural literary theory has been especially prominent, including deconstructionist theory. Rhetorical study, in particular, demonstrates the extent to which scientific theories, explanations, and descriptions of the world are not so much dependent upon the world in itself as on discursive conventions. Traditions of language use construct what we take to be the world. The third context of ferment, the *social*, may be traced

to the collective scholarship in the history of science, the sociology of knowledge, and social studies of science. Here the major focus is on the social processes giving rise to knowledge, both scientific and otherwise.

In what follows, I shall briefly outline a number of the most widely shared agreements to emerge from these various movements. To be sure, there is active disagreement both within and between participants in these various traditions. However, there are at least three major lines of argument that tend to link these traditions and to form the basis of contemporary social constructionism.

The Social Origins of Knowledge

Perhaps the most generative idea emerging from the constructionist dialogues is that what we take to be knowledge of the world and self finds its origins in human relationships. What we take to be true as opposed to false, objective as opposed to subjective, scientific as opposed to mythological, rational as opposed to irrational, moral as opposed to immoral is brought into being through historically and culturally situated social processes. This view stands in dramatic contrast to two of the most important intellectual and cultural traditions of the West. First is the tradition of the individual knower, the rational, self-directing, morally centered, and knowledgeable agent of action. Within the constructionist dialogues, we find that it is not the individual mind in which knowledge, reason, emotion, and morality reside, but in relationships.

The communal view of knowledge also represents a major challenge to the presumption of truth, or the possibility that the accounts of scientists, or any other group, reveal or approach an objective truth about what is the case. In effect, propose the constructionists, no one arrangement of words is necessarily more objective or accurate in its depiction of the world than any other. To be sure, accuracy may be achieved within a given community or tradition – according to its rules and practices. Physics and chemistry generate useful truths from within their communal traditions, just as psychologists, sociologists, and priests do from within theirs. But from these

often competing traditions, there is no means by which one can locate a transcendent truth, a “truly true.” Any attempt to establish the superior account would itself be the product of a given community of agreement.

To be sure, these arguments have provoked antagonistic reactions among scientific communities. There remain substantial numbers in the scientific community, including the social sciences that still cling to a vision of science as generating “truth beyond community.” In contrast, scientists who see themselves as generating pragmatic or instrumental truths find constructionist arguments quite congenial. Thus, for example, both would agree that while Western medical science does succeed in generating what might commonly be called “cures” for that which is termed “illness,” these advances are dependent upon culturally and historically specific constructions of what constitutes an impairment, health and illness, life and death, the boundaries of the body, the nature of pain, and so on. When these assumptions are treated as universal – true for all cultures and times – alternative conceptions are undermined and destroyed. To understand death, for example, as merely the termination of biological functioning would be an enormous impoverishment of human existence. If a nourishing life is of value, there is much to be said of those who believe in reincarnation, the Christian vision of “a life hereafter,” or the Japanese, Mexican, or African tribal views of living ancestor spirits. The constructionist does not abandon medical science but attempts to understand it as a cultural tradition – one among many.

The Centrality of Language

Central to the constructionist account of the social origins of knowledge is a concern with language. If accounts of the world are not demanded by what there is, then the traditional view of language as a mapping device ceases to compel. Rather, constructionists tend to draw from Wittgenstein’s (Wittgenstein 1953) view of meaning as a form of language game. And, given that games of language are essentially conducted in a rule-like fashion, accounts of the world are governed in significant degree by conventions of

language use. Empirical research could not reveal, for example, that “emotions are oblong.” The utterance is grammatically correct, but there is no way one could empirically verify or falsify such a proposition. Rather, while it is perfectly satisfactory to speak of emotions as varying in intensity or depth, discursive conventions for constructing emotional life in the twenty-first century do not happen to include the adjective “oblong.”

Social constructionists also tend to accept Wittgenstein’s view of language games as embedded within broader “forms of life.” Thus, for example, the language conventions for communicating about human emotion are linked to certain activities, objects, and settings. For the empirical researcher, there may be “assessment devices” for emotion (e.g., questionnaires, thematic analysis of discourse, controlled observations of behavior) and statistical technologies to assess differences between groups. Given broad agreement within a field of study about “the way the game is played,” conclusions can be reached about the nature of human emotion. As constructionists also suggest, playing by the rules of a given community is enormously important to sustaining these relationships. Not only does conformity to the rules affirm the reality, rationality, and values of the research community, but the very *raison d’être* of the profession itself is sustained. To abandon the discourse would render the accompanying practices unintelligible. Without conventions of construction, action loses value.

The Politics of Knowledge

As indicated above, social constructionism is closely allied with a pragmatic conception of knowledge. That is, traditional issues of truth and objectivity are replaced by concerns with that which research brings forth. It is not whether an account is true from a God’s eye view that matters, but rather, the implications for cultural life that follow from taking any truth claim seriously. This concern with consequences essentially eradicates the long-standing distinction between *fact* and *value*, between is and ought. The forms of life within any knowledge-making community represent and sustain the values of that community.

In establishing “what is the case,” the research community also places value on their particular metatheory of knowledge, constructions of the world, and practices of research. When others embrace such knowledge, they wittingly or unwittingly extend the reach of these values.

Thus, for example, the scientist may use the most rigorous methods of testing emotional intelligence and amass tomes of data that indicate differences in such capacities. However, the presumptions that there is something called “emotional intelligence,” that a series of question and answer games reveal this capacity, and that some people are superior to others in this regard are all contingent on the conventions of a given tradition or paradigm. Such concepts and measures are not required by “the way the world is.” Most importantly, to accept the paradigm and extend its implications into daily life may be injurious to those people classified as inferior by its standards.

This line of reasoning has had enormous repercussions in the academic community and beyond. This is so especially for scholars and practitioners concerned with social injustice, oppression, and the marginalization of minority groups in society. Drawing sustenance in particular from Foucault’s work, a strong critical movement has emerged across the social sciences, a movement that gives expression to the discontent and resistance shared within the broad spectrum of minorities. In what sense, it is often asked, do the taken for granted realities of the scientist sustain ideologies inimical to a particular group (e.g., women, people of color, gays and lesbians, the working class, environmentalists, the elderly, the colonized) or to human well-being more generally? Traditional research methods have also fallen prey to such critique. For example, experimental research in psychology is taken to task not only for its manipulative character but its obliteration of the concept of human agency.

These three themes – centering on the social construction of the real and the good, the pivotal function of language in creating intelligible worlds, and the political and pragmatic nature of discourse – have rippled across the academic disciplines and throughout many domains of

human practice. To be sure, there has been substantial controversy, and the interested reader may wish to explore the various critiques and their rejoinders (see, for example, Gergen 2001, 2009; Hacking 1999). However, such ideas also possess enormous potential. They have the capacity to reduce orders of oppression, broaden the dialogues of human interchange, sharpen sensitivity to the limits of our traditions and to their potential offerings, and to incite the collaborative creation of more viable futures.

Self-Identification

Science

Social constructionists do not generally identify themselves as scientists, at least in terms of the positivist/empiricist view of science that largely prevails today. More generally, they raise questions about the definition of science and what is at stake politically and socially in attempting to generate strong borders of exclusion. At the same time, many constructionists carry out scientific work of the traditional kind, viewing such work, however, as itself a form of construction.

Religion

Constructionists do not generally view themselves as participating in a religion, at least in terms of a commitment to theistic or spiritual beliefs. At the same time, many constructionists participate in religious or spiritual activities, understanding these activities as traditions of meaning that carry with them valued implications for cultural life. Simultaneously, various religious groups are finding social constructionist ideas useful for enriching church and pastoral practices (Hermans et al. 2002).

Characteristics

Constructionists are similar both to the traditions of science and religion inasmuch as they are engaged in creating and sustaining particular constructions of reality, reason, and value. They

differ, however, in their avoidance of the kinds of foundational claims that are common to both traditional science and religion. Social constructionism is not a belief system; rather it is an array of ideas and related practices that many view of enormous potential in helping the world's peoples live together amicably. In part, this is so because constructionist ideas invite understanding and collaboration across traditions as opposed to competition.

Relevance to Science and Religion

For many constructionists, the interest in science and religion stems from the fact that these are institutions of pivotal significance in the contemporary world in their constructions of reality and value. However, of particular significance in recent years has been the way in which constructionist ideas inform the emerging dialogues between science and religion. By viewing each of these traditions as "truth generating" within its domain of assumptions and practices, one may avoid the problematic tendencies of searching for convergences on the one hand and mounting critique on the other. Both such tendencies move toward a world of singular truth, which is ultimately oppressive and pragmatically debilitating.

Sources of Authority

The general orientation to what are traditionally viewed as "sources of authority" within the social constructionist dialogues is skeptical. Constructionists tend to be critical of authority structures and to opt for all-inclusive dialogue.

Ethical Principles

In general, one may find in the constructionist dialogues two orientations toward ethical principles. The first is critical of all such principles. As it is variously argued, ethical principles are problematic at the outset because there are no

unambiguous means of deriving action from abstract principles. More importantly, such principles tend to reinforce a certain way of life, relegating others to a secondary status. In effect, they are exclusionary, and thus conflict provoking. Further, principles have a tendency to terminate the kinds of dialogues that are essential for understanding human action within what are inevitably unique circumstances.

The second orientation toward ethical principles is to locate within constructionist ideas an underlying set of ethical presuppositions. Some find, for example, that constructionist ideas favor pluralism, integration, collaboration, justice, tolerance, and democracy.

Key Values

The issue of values within social constructionist dialogues is controversial. As just outlined, one may see in constructionist thought a commitment to certain ethical principles or values. However, such claims are controversial primarily because a strong commitment to any value system may have the ultimate effect of bringing an end to the process of meaning, making out of which values are created.

Conceptualization

All the concepts included below are viewed as human constructions. They are created within cultures during specific historical periods and are used within these cultures for carrying out their ways of life. However, because there are multiple cultures and historical transformations in meaning, these concepts may be freighted with multiple meanings and usages. Most constructionist work with these concepts has had the purpose of denaturalizing them, opening them to critical inquiry, and offering alternative ways of thinking and practicing. In some of these cases, particularly where conflict is sharp and potentially lethal, new projects of dialogue are mounted. Some of this work is reflected in the following comments:

Nature/World

Important critical work has questioned the common binary between the natural world and the human or cultural world. As it is argued, this distinction has typically privileged the human world with resulting ecological catastrophe.

Human Being

Lively discussion of the various conceptions of the human being has taken place within constructionist writings. Recent attempts are aimed at moving beyond the conception of humans as self-contained organisms and toward a view of human action as an outcome of relational embeddedness.

Life and Death

Important constructionist work in this case has been devoted to defusing the conflict between pro-life and pro-choice factions. As noted, a constructionist orientation favors action-oriented contributions to society.

Reality

Whatever is to be said about reality, constructionists argue, is always issuing from a particular culture. Beyond these constructions, there is nothing that can be said. Foundational arguments about the nature of reality are futile.

Knowledge

All claims to knowledge are social constructions. This view invites a pragmatic orientation to knowledge making and a reflexive posture in evaluating the values inherent in any contribution to knowledge.

Truth

Like the concepts of reality and knowledge, constructionists view “truth” as a potentially dangerous category. Those who claim truth beyond a tradition are divisive. However, by viewing truth claims as means of securing trust within traditions, we can appreciate the use of the concept.

Perception, Time, and Consciousness

In viewing these as constructions, we avoid interminable debate and inquire into the utility and social value inherent in any given account.

Rationality/Reason

Rationality has come under critical fire among constructionists because of the way in which the concept has been used to valorize certain traditions and classes. In general, constructionists view reason in terms of discourses congenial with various traditions.

Mystery

Many constructionists celebrate the concept of mystery, as it invites curiosity and leaves paths to further dialogue open.

Relevant Themes

Of central concern to science and religion are issues of morality and materialism. While science tends to take no stand in the former case, those in spiritual traditions see the scientific preoccupation with materialism limited. Social constructionist ideas are useful here in inviting moral pluralism, on the one hand, and an appreciation (and the limitations) of multiple realities (including both material and spiritual) in terms of global contribution.

Social Interaction Explanations

Patricia E. Erickson
Department of Sociology, Anthropology, and
Criminal Justice, Canisius College OM-016 C,
Buffalo, NY, USA

Social interaction explanations examine how people become criminals and emphasize that criminal behavior is learned behavior. Sociologist Edwin

Sutherland developed the theory of differential association in the 1920s and 1930s to explain how people become criminals. He maintained that criminal behavior is learned in interaction with others and that criminals learn to favor criminal behavior over noncriminal behavior.

Persons and Objects

We experience interactions with persons in social encounters and manipulations of physical objects every day. Although we are usually not asked to reason about this, there seems to be a fundamental difference between persons or human beings and physical objects, which we are usually not aware of. However, we are making use of this distinction continuously and automatically throughout our everyday life. This difference refers to the following aspects. Whereas the behavior of persons can only be successfully explained or predicted by reference to the inner experience of the person including perceptions, thoughts, feelings, desires, or intentions-to-act, there is no need to assume anything

comparable to such an inner experience if we are asked to explain or predict the behavior of physical objects or “things.” The behavior of persons can only be explained on the basis of psychological rules (“folk psychology”) that we learn and acquire during our ontogenetic development; the behavior of physical objects can be explained on the basis of natural laws in the framework of classical Newtonian physics (“folk physics”). The behavior of persons can be predicted only on the basis of probabilistic estimates: In a given particular instance of a social encounter, we can never be sure how an interacting human will react (e.g., smiling at another person and her/his reaction to the smile); the behavior of physical objects can be predicted in a deterministic fashion: If we are sufficiently informed about the different forces that influence a given object, we can by necessity predict how it will behave (e.g., a ball running down a slope because of gravity). In contrast, there are no natural laws in the strict sense that can guide us during processes of person perception or impression formation. This fundamental distinction was put forward by Fritz Heider, the founder of the so-called attribution theory in the field of social psychology. He distinguished between “person perception” or “social perception” in contrast to “thing perception” or “nonsocial perception” (Heider 1958). In the following, we focus on experiences and processes related to the social domain.

Naturalistic Account

We as persons or human beings experience mental phenomena, such as perceptions, thoughts, feelings, desires, or intentions-to-act, from a first-person-perspective. Complementary to this, mental phenomena can be reconstructed from a third-person-perspective as “the subjective experience of cognitive function” (Fuster 2003). Following a naturalistic view, which holds that all relevant cognitive processes and their neural mechanisms can be studied and fully understood by employing the methodology of natural sciences including cognitive neurosciences, our mental phenomena or conscious

experiences are closely linked to their underlying neural mechanisms to which they correspond.

More precisely, the philosophical identity theory as prominently positioned in the philosophy of mind postulates that our mental phenomena are identical with neural mechanisms with which they can be (extensionally) identified, although the (intensional) content or “meaning” of mental phenomena and neural mechanisms are clearly different (Vogeley and Seitz 1995). In other words, whereas mental phenomena are experienced in a subjective space-time system, cognitive processes and neural mechanisms are observables in an objective space-time system (Kuhlenbeck 1981). Teleologically, consciousness provides an integrated internal representation of the outer world and one’s own organism based on experiences and memories providing reflected responses to the needs of our environment (Vogeley et al. 1999).

Based on this theoretical grounding, cognitive neuroscience has started to identify and address increasingly complex explananda during the last decade including self-consciousness and intersubjectivity. More recently, processes that are related to interaction and/or communication in social encounters between human agents have been studied systematically and extensively. These research activities have constituted the new research field of “social cognitive neuroscience” or “social neuroscience” (Ochsner and Lieberman 2001; Adolphs 2009; Schilbach et al. in press), from which already monographs, edited volumes, and academic journals have emerged.

Self-Other-Differentiation and Self-Other-Exchange

It appears useful to introduce a rudimentary taxonomy that covers at least three essential distinctions. First, the processes that focus on self-other-differentiation (as the ability to differentiate between one’s own and other person’s mental states; Vogeley et al. 2004; David et al. 2006, 2007) are to be differentiated from processes serving self-other-exchange (as the ability to share or exchange mental states with

others; Vogeley et al. 2001; Schilbach et al. 2006). This distinction is a crucial basic step to avoid a possible confusion of whether a given mental phenomenon refers to or can be traced back to oneself or not: Survival in a social world clearly requires the ability to distinguish between oneself and others as the “owner” or “agent” of mental states. Disturbances of this important capacity might give rise to the psychopathological phenomenon of ego-disturbances during which the owner or initiator of experiences or movements can no longer be adequately attributed, neither to oneself nor to others.

A “minimal self” as prerequisite of social cognition (Gallagher 2000; Vogeley and Gallagher 2011) comprises at least the following essential features as key constituents: (1) the experience of ownership (with respect to perceptions, judgments, etc.; e.g., expressed by the adequate use of personal pronouns) or agency (with respect to actions, thoughts, etc.; e.g., expressed by the experience that oneself causes and controls one’s own actions); (2) the experience of “perspectivalness” with conscious states being “centered” around myself, incorporated in my body, and embedded in a literally spatial, body-centered perspective; and (3) the experience of unity that is associated with a long-term coherent whole of beliefs and attitudes that are consistent with preexisting autobiographical contexts and that can, for instance, be empirically addressed by studies on autobiographical memory (Fink et al. 1996).

Based on the capacity of self-other-differentiation, we need to ground our everyday behavior in human encounters on adequate judgments and perceptions of other persons, also referred to as the so-called “theory of mind” or mentalizing capacity. A very prominent strategy to study such ascriptions of mental states to others in an inferential, rule-based manner refers to “theory of mind” paradigms that require the prospective modeling of the knowledge, the attitudes, or beliefs of another person (Vogeley et al. 2001). A very important key region among others that is involved in a variety of different social cognitive tasks including “theory of mind” tasks and mentalizing is the medial prefrontal cortex, a part of the frontal lobe of the human brain (Amodio and Frith 2006).

Levels of Processing

Being aware of one’s own mental states and being able to “read” other persons’ minds or to “understand” or “simulate” what they are experiencing are clearly two different capacities. A very important second distinction, presumably orthogonal to the first one that needs to be emphasized is related to different levels of processing of social information. Cognitive processes can, in general, be either implicit or explicit: Implicit information processing refers to a comparably fast, automatic, pre-reflexive mode that is employed, for instance, during nonverbal behavior. In contrast, explicit information processing comprises processes in a comparably slow, reflexive, inferential format, such as stereotypes or processing based on explicit rules (Lieberman 2007; Frith and Frith 2008). Only a part of psychological processes are experienced consciously and processed on a reflexive, inferential level, as shown for the processing of nonverbal communication cues (e.g., Burgoon et al. 1996). Whereas nonverbal cues including mimic expressions (Schilbach et al. 2006), gestures (Lindenberg et al. 2012), or social gaze (Kuzmanovic et al. 2009) are processed in a fast, automatic, pre-reflexive, and implicit manner, social interactions can also be based on explicit rules, such as stereotypes, that are processed in a comparably slow, reflexive, and inferential manner, and presumably more often in a controlled way (Lieberman 2007; Barsalou 2008).

Among nonverbal communication cues gaze behavior is an important and salient signal for social interest and the intention to communicate, thus indicating mental states of significant others (Argyle and Cook 1976). “Social gaze” is crucially modulated by various dynamic characteristics among which gaze duration is of particular relevance. We investigated the neural correlates of participants while being gazed at with varying gaze duration. Increasing gaze duration resulted in an increased likeability rating and increased neural activation again in the medial prefrontal cortex (Kuzmanovic et al. 2009). This process of gaze evaluation can be understood as a comparably late stage of processing implemented in the medial prefrontal cortex.

However, these levels of processing should be conceptualized as a continuum of different levels of processing resulting in a flexible capacity of person perception that is performed either automatically or in a controlled manner, depending on the data available.

Gaze can also establish triadic relations between self, other, and the world via the modulation of attention of others or “joint attention,” an important precursor of social cognition (Moore and Dunham 1995). It has been suggested that it might be the motivation to participate in joint attention that leads to shared, social realities as a unique aspect of human cognition (Tomasello et al. 2005). To realize a truly interactive paradigm we developed an eye-tracking setup allowing to track a participant’s gaze behavior and to contingently control the gaze behavior of a computer-animated character visible on the screen (Schilbach et al. 2010; Vogeley and Bente 2010). Participants were instructed to lead the gaze of the other person toward one of three objects by looking at it. The gaze behavior of the other was made responsive to the participant’s gaze and was systematically varied so that the participant had to follow the gaze (joint attention) or not. Alternatively, participants were asked to respond to the other by looking at the same or at another object. Employing functional magnetic resonance imaging, the analysis demonstrated that joint attention was associated with a recruitment of the medial prefrontal cortex. The second interesting finding was that directing someone else’s gaze toward an object activated the brain’s reward system (ventral striatum). This finding could correspond to the hedonic and motivational aspects of sharing attention with others or could reflect that control of others motivates to engage with others (Fiske and Dépret 1996).

Cultural Universality and Diversity

In addition, during the last few years researchers in the field began to take into account the potentially considerable influence of culture on self-construct development and group formation also referred to as “independent” or

“interdependent” self (Markus and Kitayama 1991; Singelis 1994; Vogeley et al. 1999), which in turn might influence other domains of human cognition (Markus and Kitayama 1991; Nisbett and Masuda 2003). The issue of cultural influences should be taken into account as a third distinction. “Culture,” however, is not a clearly defined, rigid body of rules that shapes each and every individual of a given culture in a similar, uniform way, but is highly dynamic and continuously interacts with its constituting individuals, any individual can be part of different cultures at the same time (Hofstede 2003). A culturally sensitive neuroscience must take into account the dynamic character of culture, the dialectic exchange between individual and collectivity, and the recursive “looping effect” of cultural classifications on social practices and identity processes (Hacking 1999; Vogeley and Roepstorff 2009).

Focusing on the key term culture, it is important to differentiate between a “universal” and a “particular” concept of culture resembling the proposals of cultural universality and cultural diversity. Whereas the universal concept holds that culture is a result of our capacity to interact and communicate with other human beings and is universal for our species (Tomasello et al. 2005), the particular concept emphasizes the differences of cultural backgrounds that influence and shape our cognitive capacities and lead to considerable variations across different cultural settings (Kitayama and Cohen 2007) leading to the necessity to introduce culture as independent variable into psychological experiments, however, with a number of caveats (Vogeley and Roepstorff 2009).

Many studies in the field of “cultural neuroscience” (Chiao and Ambady 2007) that included culture as an independent factor into functional neuroimaging studies addressed empirical indicators of culture such as language or nationality. For instance, based on Kelley et al. (2002) one of the early cultural neuroscience studies asked test persons to attribute and ascribe certain attitudes toward oneself as compared to one’s own mother and other persons comparing a Chinese population and a so-called Western population

Social Neuroscience, Fig. 1 This figure illustrates three different distinctions that should be considered in the domain of social cognitive neuroscience. These include (1) the distinction of self-other-differentiation and self-other-exchange as the different “references,” (2) the

distinction of intuitive, pre-reflexive, automatic and inferential, reflexive, controlled processes as different “levels,” and (3) the distinction of cultural universality and cultural diversity

(Great Britain, USA, Australia, and Canada). Ascription of mental states to oneself and to their own mothers resulted in the common activation of the medial prefrontal cortex across the conditions in the Chinese population, but revealed a distinct pattern of activation in the Western population (Zhu et al. 2007), leading to the conclusion that the different populations process information about themselves and their mother differently. Different religious experiences were studied by Han et al. (2008) that resulted in a differential activation again of the medial prefrontal cortex during self-referential processing in nonreligious and Christian participants (Fig. 1).

Neural Mechanisms of Social Cognition

These concepts and observations lead us to a consideration of the underlying neural mechanisms. The empirical findings cited above should not lead to the neo-phrenological impression that the medial prefrontal cortex is “the” social cortex of the brain that is always specifically recruited during social cognition. This would imply a “reverse inference” that tries to infer the functional role from the localization of brain activation. This, however, is only possible if the brain region is selectively and specifically recruited only during certain cognitive tasks (Poldrack 2006). As was shown in a meta-analysis this is not the case for the medial prefrontal cortex that is involved in a rich variety of different cognitive tasks (Van Overwalle 2009).

The functional role has to be identified instead as a basic process that can be understood as a common denominator of the variety of different cognitive functions recruiting this region. In the case of the medial prefrontal cortex, it was suggested that its essential function is to contribute to “inexact, probabilistic, internally generated” cognition (Mitchell 2009). This is intriguing as it nicely corresponds to the distinction introduced by Heider (1958) on “person perception” that is characterized by an inherent ambiguity and uncertainty as opposed to “thing perception” that can be understood deterministically.

Another strategy has been to search for the networks of activated brain regions and not only single regions. Social neuroscience has revealed essentially two different systems recruited during social cognitive processes as follows: (1) the “social brain” or “mentalizing” network including essentially the anterior medial prefrontal cortex, the temporoparietal cortex and superior temporal sulcus, and the temporal pole (Frith and Frith 1999; Adolphs 2009), and (2) the so-called human “mirror neuron system” covering superior parietal and premotor regions (Rizzolatti and Craighero 2004). However, it is still an open debate that needs more thorough empirical research dedicated to this research question: What could be the differential functional roles of both systems? One plausible suggestion is that as soon as the attribution of mental states to others is involved the mentalizing network is activated, whereas the

mirror neuron system is recruited when a real or virtual motor component is involved, for example, in actions, simulations, or imaginations thereof (Vogeley et al. 2004; Keysers and Gazzola 2007; Wheatley et al. 2007). Another suggestion, that does not necessarily contradict the first view, assumes that the mirror neuron system correlates with early stages of social cognition such as the detection of motor expertise and might putatively also underlie the fast processing of “first impressions” in social encounters that are generated on the basis of facial expressions or gestures. In contrast, the social neural network is recruited during comparably “late” stages of evaluation of socially relevant information (Santos et al. 2010). Social cognition appears to constitute a “natural kind” of our cognitive capacities that are characterized by “the dependence on a qualitatively distinct class of mental representations” (Mitchell 2009). Seemingly different cognitive phenomena (including thinking about oneself, accessing one’s attitudes, experiencing emotions, inferring other person’s mental states, etc.) have in common the characteristics of “fuzzy,” probabilistic, and internally generated cognition, and on a neural level they share the same substrate, the medial prefrontal cortex (Mitchell 2009).

Notably, these key regions of the social neural network have also demonstrated to be active during the so-called resting states or baseline conditions that are characterized by the absence of any external instruction of an experimenter. This specific pattern of distribution of baseline activation has been identified as the so-called default mode of brain function or default network and was first studied by Raichle et al. (2001). Meta-analytical studies demonstrate a significant overlap between the social neural network and the default network (Buckner et al. 2008; Schilbach et al. 2012). Intriguingly this default network can be observed in humans irrespective of the task they are involved in and the methodology with which brain activity is measured and is also observed in other mammals (Vincent et al. 2007) and can, thus, be considered a neurobiologically universal building principle of mammalian brains.

This empirical observation of the overlap of both systems stimulates the speculation that one major cognitive function of the neural default network could be in fact social cognition which conversely implies that humans have a disposition for social cognition that is reflected in this default network. This convergence supports the hypothesis that this disposition for social cognition is neurobiologically instantiated and can be assumed to be disturbed during disturbances of social cognition. An even more ambitious move would be to assume that the default network is a neurobiological universal in humans and that social cognition is its key function. This would allow to conclude that social cognition itself is a universal cognitive capacity in humans. Notably, this is in concordance with the proposal of Michael Tomasello (Tomasello et al. 2005) who suggests that social cognitive capacities were a prerequisite for the development of human culture in a universal sense and were relevant for the development of the whole genus of *Homo sapiens*. According to this plausible proposal, social consciousness is what makes us human, and social cognitive neuroscience studies the neurobiological mechanisms that underlie these specifically human cognitive capacities.

Description

By Gordon Allport’s classic definition, ► [social psychology](#) is the scientific attempt to understand and explain how the thought, feeling, and behavior of individuals are influenced by the actual, imagined, or implied presence of others (Allport 1954). This definition has been influential and instructive for researchers’ partitioning of the field at many stages of its development from the earliest defining works of Ross and McDougall in 1908 through the conceptual and methodological pluralism of contemporary researchers. The attributes Allport chose as descriptors of the field also summarize a significant portion of current work, including cognitive models of attitude change, links between emotional response and aggressive behavior, interpersonal interaction in close relationships, and the implications of counterfactual thinking, each respectively corresponding to components of the classical definition (Gilbert et al. 1998).

Some areas of inquiry have fluctuated in the amount of attention accorded by researchers. For instance, studies of automaticity and the influence of the unconscious in social interaction are currently impactful in the literature, though scarce in earlier decades, especially during the periods dominated by behaviorist perspectives. Other topics have been important substantive areas within the field since its organization at the beginning of the twentieth century.

Stereotyping, prejudice, and discrimination are phenomena that remain current despite a relatively long history of investigation – a 1934 study by LaPiere famously reported a lack of strong correlation between self-reported attitudes and behavioral measures of discrimination. This finding led to an intense effort to understand the conditions under which attitudes and relevant behavior would correspond in a predictable way (Eagly and Chaiken 1993). Modern researchers address such phenomena with concepts such as implicit attitudes: Evaluations of people or other objects that predict behavior yet cannot be unexpressed by the individual. In settings from the courtroom to neighborhood backyards, implicit attitudes induce changes in judgment of others outside of awareness, either of the subject or object of the prejudice. While it is clear that implicit attitudes can have a negative impact on interpersonal interactions in matters of prejudice, other examples illustrate the adaptive value of nonconscious processes: Research in sexual attraction and mate selection shows that males tend to favor a particular waist-to-hip ratio of female partners despite the fact that they are not aware of the preference either during or subsequent to mate selection. This preference represents an implicit preference for body types most likely to bear reproductive success, and therefore the implicit attitude that drives this favoritism serves an adaptive utility that the conscious mind is simply not aware of in most situations (Tooby and Cosmides 1992).

Recently, demonstrated effects such as these have lead to some controversy over exactly how “smart” the unconscious process is and under what conditions nonconsciously driven behaviors are adaptive. For instance, the unconscious may have adaptive advantages in addressing some problems (e.g., optimal mate selection or adjusting attention appropriately to external stimuli), yet be wholly inappropriate for others: Driving down an unfamiliar road is best suited for conscious processes. Although psychologists have been aware of the impact and relevance of the unconscious since before the work of Freud, ascertaining properties of interest such as the amount of information that can actually be

communicated via subliminal perception and its ultimate impact on attitudes and behavior change is an effort undertaken with enthusiasm by modern researchers (Hassin et al. 2005).

In addition to the content of study, a defining factor of the social psychological endeavor is the array of methodologies employed by researchers in the discipline. These methodologies are rooted in the rules of scientific observation, experimentation, mathematical and statistical analysis of data, and the scientific exposition of results when communicating to others in the field. Recent methodological developments include the use of meta-analysis to aggregate studies and estimate effect sizes across a wide variety of contexts, the use of structural equation modeling to assess the correlational structure of variables and factors in studies involving many interrelated variables, such as is common in personality research, and computer simulation to model a sequence of many events or interactions over a period of time, as in studies of the development of emergent segregation effects in housing due to group-based preferences (Reis and Judd 2000). The methodologies employed are not topic specific, and the field has generally benefited from multimethodological approaches in understanding a variety of phenomena from the impact of group-level pressures toward conformity in political decision-making to the most effective attributes of successful advertising campaigns.

Self-Identification

Social psychology operates within the scientific tradition of objective, replicable methodologies and the systematic accumulation of knowledge and is therefore termed a science by its practitioners (Campbell and Stanley 1963; Campbell 1988).

Phenomena within the realm of social psychological interest are generally observable, measurable, and replicable. For instance, the impact of a conceptual prime, even a nonconsciously administered one within studies of automaticity, may be scientifically assessed by observing

the subsequent behavior of the participant: An experimental manipulation of a prime such as describing the behavior of an elderly vs. athletic person can induce subsequent observable differences in participant behavior such as walking speed – participants are more likely to take longer to walk down the hallway if they received the elderly prime. Although the mechanism of the impact of the prime is thought to be contained in the mind and is by nature unobservable, the difference in the behavioral outcome is measurable and therefore communicable to other researchers and amenable to replication efforts in other laboratories (Hassin et al. 2005). Other examples of observable psychological effects include the impact of attitudes on behavior such as the increased likelihood of purchasing of luxury products like candy bars, the impact of persuasion on attitude change and resultant behavior such as voting for Democrats rather than Republicans, and the impact of group membership on usage of stereotypes as operationalized as differences in judgment or impression formation and the ability to detect prejudice and social discrimination (Eagly and Chaiken 1993). Despite the varying objectivity of some of the processes involved in many of these effects, all have been investigated utilizing one or more of the following methodologies: laboratory experimentation, content analysis of historical documents, survey experimentation and analysis, and correlational and field methods. All effects such as these are open to disconfirmation in replication efforts (Campbell and Stanley 1963; Campbell 1988).

Ultimately, the research endeavor is termed scientific due to the ability of researchers to communicate, amend, and/or contradict earlier findings and interpretation, thereby advancing theory and understanding of the phenomena of interest to subsequent researchers. Whereas religions tend to draw knowledge and understanding of the world from static sources of authority (e.g., holy books), the body of scientific knowledge is dynamic in nature and always susceptible to revision, even after extremely long periods of success (e.g., Newton's understanding of gravity).

Characteristics

The focus on the interaction between external, social causes of behavior, and internal, psychological causes of behavior is the heart of the distinction between social psychology and other related disciplines such as psychology and sociology. Researchers in psychology as a whole generally focus on phenomena intrinsic to individuals such as biological processes of the brain, sensation and perception, analyses of genetic relationships to behavior such as learning, and other purely psychological characteristics such as intelligence. On the other hand, sociological researchers generally focus on group-level phenomena such as population distribution and the successes and failures of social and political movements. In short, social psychology distinguishes itself from these fields though its focus is on social processes both as causes and effects of individual psychological phenomena. It is the interaction of the individual- and group-level variables that is of most interest to social psychologists.

Social psychology is practiced within both the psychological and sociological traditions. The interdisciplinary differences are evident in conceptual focus: Sociological social psychology draws its perspective from theories such as the ► [symbolic interactionism](#) of George Herbert Mead (Blumer 1969) and emphasizes the influence of individual-level variables on macroscopic social analyses in studying topics such as social structure and group dynamics. Psychological social psychologists place greater emphasis on the impact of social context on individual-level variables in studying effects such as social influence, group perception, and attitude change. In psychological social psychology, the theoretical basis of these and other effects have shifted often over the last decades with emphases stemming from functionalist, behaviorist, attributional, social cognitive, and currently multimethodological, polytheoretic approaches. Methodological differences are also present between the subdisciplines: Sociological social psychologists are more likely to use sociometric data, unstructured interviews, social

surveys, observational techniques, and archival and qualitative data analytic research methods, while psychological social psychologists are more likely to rely on experimental methodologies in their mode of inquiry. Importantly, professional publication outlets and professional society memberships for each of the subdisciplines are largely nonoverlapping. However, despite differences in theoretical foundation as well as methodology, social psychologists from both traditions share interest in largely the same domain of human behavior: the interaction of the psychology of the individual with the social environment. The differences may be seen as a matter of emphasis rather than kind: Whereas psychological social psychologists give primacy to the individual's psychology as shaped by the social environment, sociological social psychologists give primacy to the social construction of self, as shaped by group-level differences. The differences between the subdisciplines may amount more to differences in the theoretical training that researchers receive to address and explain the same basic behavioral phenomena than substantive content boundaries between sociology and psychology.

Relevance to Science and Religion

The discipline of social psychology takes for granted that the appropriate method of inquiry is scientific in nature. While religious methods of inquiry are usually more subjective by primarily relying on introspective self-report, scientific social psychology relies on methods that are objectively verifiable. Even studies of cognition or emotion ultimately use behavioral variables as indicators of "black box" contents – in addition to physiological or observational measures, self-report instruments such as questionnaires and surveys of experience are subject to analyses of reliability and validity. In short, the essence of the scientific aspect of social psychology is that study results must be replicable at other times by different researchers in different laboratories with different participants. External peer review of results and interpretation is often used to

ensure that studies entering the literature meet the criteria of high scientific rigor and substantive contribution the field.

However, social psychologists acknowledge that there are many questions important to the human experience that is not answerable with this sort of approach. It is taken for granted that scientific methodologies cannot address the myriad of moral issues surrounding the determination of ethical practices, goals of research, and applications of findings. For instance, while it may be possible to assess the potential risk of a human or animal participant in a particular research project, weighing this risk against the potential benefits of the research to society is a value judgment that in some cases will be a cause of disagreement between researchers and disciplines or between the scientific and nonscientific communities. These roots of these values lay more within the domain of religion, or more generally, philosophy, rather than the scientific method. However, what current scientific practices can do is objectively study the effectiveness of policies and practices in reaching goals driven by these values. For instance, a social psychological analysis of interpersonal relationships may find correlates of love and friendship but cannot answer the moral questions about whether there is a need for love and friendship in order to live an objectively fulfilling life. Furthermore, the primarily sociological processes by which people in groups come to consensus on the answers to these moral issues and the primarily psychological process for each person deriving their own answers within the social context are both within the domain of social psychological inquiry; however, the content of these moral issues is largely beyond the scope of the scientific endeavor as it now stands.

Sources of Authority

The root authoritative sources in social psychology are textual, and found within peer-reviewed journals. Articles that are cited by others' work as foundational for future research endeavors are considered more authoritative as indicators

of the current direction of the field. Individual social psychologists gain authority by publishing frequently and/or having their publications frequently cited by other researchers. Largely influential lines of research are often synthesized in book form, which may or may not be peer reviewed, but will often consist of a collection of chapters assembled by an editorial team. The lead investigators are more likely to be invited to edit or publish textbooks and speak at major conferences; these contributions are also cited by other authors, adding to their influence.

Specific publications of historical and current interest in defining the field include *The Principles of Psychology* (1890), by William James, as important to the field of psychology as a whole, and his chapter on the Self continues to be influential in current social psychological considerations. As symbolic interactionism is a guiding theory in sociological approaches to social psychology, the work of George Herbert Mead is considered authoritative, as are other works summarizing his perspective; Blumer's *Symbolic Interactionism: Perspective and Method* (Blumer 1969) is a prominent example. Fritz Heider's *The Psychology of Interpersonal Relations* (1958) was and continues to be an inspirational source for research on cognitive consistency, which culminated in many ways in the massive 6-editor, 84-chapter volume *Theories of Cognitive Consistency: A Sourcebook* published in 1968. Susan Fiske and Shelley Taylor's advanced text *Social Cognition* (1991) emphasized the importance of the processes involved in perceiving, remembering, and interpreting information about ourselves and others. All editions of *The Handbook of Social Psychology* (first edition published 1954, most recent edition, 1998 (Gilbert et al. 1998)), which summarize recent research in the most important and active subfields of social psychology, are considered important summary sources of authority.

Ethical Principles

Several experiments in the 1960s and 1970s such as those by Stanley Milgram on the social

conditions of obedience and Phil Zimbardo on the impact of social roles on prison behavior have often been cited as examples of the need for the enforcement of ethical principles in the proper use of human participants in research. For instance, Milgram's studies asked the basic question, "Under what conditions would people obey authority figures when ordered to harm an innocent person?" Even though no physical harm was administered during his experiments, participants believed that they were administering painful (and in some cases hazardous) electric shocks onto a fellow participant. Understandably, this state of affairs was the cause of great psychological distress among the participants, even after they were informed following the study that no shocks were actually given. Zimbardo's methodology required the confining of participants within a simulated prison setting and is another example cited by critics who question whether the benefits of scientific knowledge gained in the study outweigh the psychological and physical risks of the participants involved. Zimbardo found that the situational characteristics of the social and physical environment were sufficient to elicit both extremely aggressive and submissive behaviors (in the case of guards or prisoners, respectively) that are often attributed to personality characteristics. The psychological and physical trauma reported by the participants in these and some other studies caused researchers within and outside of the social psychological community to question the methods by which these risks are weighed against potential benefits to society and therefore reevaluate the guidelines that protect participants from psychological and physical harm due to research participation.

An important guide used by social psychologists is the American Psychological Association code of ethics first published in 1953 and most recently revised in 2002. Relevant ethical principles guiding the use of human subjects include informed consent (participants should be notified of the nature of the research undertaking, including their right to decline to participate, or withdraw at any time before commencing with the study), restrictions on deception (researchers

will not conduct a study that willfully deceives the participant unless it can be determined that the use of such techniques is justified by the scientific, education, or applied value that could not be obtained through nondeceptive measures), and debriefing (researchers provide a prompt opportunity for participants to obtain appropriate information about the nature, results, and conclusions of the research, and they take reasonable steps to correct any misconceptions that participants may have had). These and other principles guide researchers in contributing to the literature in a uniformly ethical manner, as defined by leaders in the psychological community (Rosenthal 1994).

Key Values

Researchers in social psychology value knowledge of social psychological processes that can be communicated and verified with others in accordance with the general rules of scientific investigation. Social psychologists utilize the scientific method to develop and validate the theories they develop, creating new knowledge that can be reliably applied to relevant social situations. Often, the most valued and influential findings are those that are particularly nonobvious or counterintuitive. An example is the fact that a participant will often say that he thought a task was more enjoyable if he was paid less to complete it. The explanation is derived from the literature on cognitive dissonance: Enjoyable tasks are often done with no reward required, so a participant is more likely to rate a task as enjoyable if he was paid a nominal amount to complete it. That is, the cognitive dissonance of completing an unenjoyable task for little reward is reduced by nonconsciously altering perception of enjoyment of the task itself. The scientific nature of the investigation is also valued as a defining feature of the discipline, so efforts to advance methodology, measurement, statistical analysis, as well as more efficient publication and communication methods (e.g., electronic journals) continue to be actively sought.

Conceptualization

Nature/World

Social psychological conceptions of nature and the world include both environmental stimuli such as particular sights and sounds (assessed via sensory organs) and more endogenous mental stimuli such as particular emotions and thoughts (often as self-reported by participants to researchers). From a macroscopic perspective, the concept of nature and the world implies the totality of individual and social experience as it is to be understood through scientific means.

Human Being

In general, this is defined as the particular type of animal known as *Homo sapiens*, largely as they exist presently. This is the primary subject of inquiry by social psychologists, although some researchers use animal models to investigate certain aspects of behavior that are not amenable to testing with humans. For instance, some aspects of sexual behavior are more easily studied using nonhuman subjects; also, social facilitation, the idea that the presence of others will increase physiological arousal and therefore increase the probability of the psychologically dominant response to a problem, has been demonstrated in humans as well as other animals such as mice and cockroaches.

Life and Death

Human life and death are generally explained through social and biological processes. Life is produced by sexual behavior which is governed by a variety of social norms and biologically driven tendencies. Death inevitably occurs when the biological organism can no longer maintain normal functioning.

Reality

Reality can be defined both subjectively and objectively. Objective reality is governed by social agreement of the interpretation of physical phenomena. For example, many people agree that the color of the sky is “blue,” and therefore that perception is objectively real. On the other hand, subjective reality is governed by an individual’s

personal interpretation of internally derived physical and mental phenomena. For example, when one experiences the physical pain of a paper cut, or feels depressed, those perceptions are subjectively real, as no other person can personally corroborate the experience. Nonreality is generally a condition where an individual's experience does not correspond to the majority of others' experience when circumstances are such that a meaningful comparison is possible. For example, if one person believes that there is a conversation going on behind him, even though it is observed that no other people around are speaking, the perception would then be judged as nonreal.

Knowledge

Knowledge is generally considered as information, either cognitive or affective in nature, which is typically gained through any of several learning processes. For instance, learning can be nonconsciously attained through modeling behavior, as is common for young children when learning social rules from their parents and roles from their peers. Alternatively, knowledge can be obtained in a very strategic, conscious manner, such as is often done by students attempting to memorize material for an upcoming exam. Social psychologists often describe knowledge and the interrelationship between different knowledge structures in terms of individual schemata, or organized cognitive modules. This understanding of the interrelatedness of knowledge is necessary in accounting for a variety of effects in studies of memory, impression formation, and role-based behavior.

Truth

Truth qua the objective set of accepted facts comprising scientific knowledge of social psychology is generally considered to be the object of agreement between perceivers. This position is closely related to consensus epistemological theories, and the critical qualification is that relevant perceivers are professional researchers indoctrinated in scientific methods and hold compatible understandings of relevant substantive topics. From a methodological perspective, a social

psychological effect is "true" to the extent that the finding can be replicated by other researchers in other places at other times. This applies not only to effects such as an increase in aggressive behavior under certain social conditions but also to social psychological understandings of the effects themselves. For instance, the truth of the frustration-aggression hypothesis – the idea that feelings of frustration are likely to induce aggressive behavior – has been progressively uncovered since its first expressions as derived from psychoanalytic theory. The effort to reduce the uncertainty of the extent and conditions under which the effect would hold true represents the scientific endeavor to seek the truth of the effect, thereby progressively solving the mystery inherent in the previous uncertainty regarding the phenomena (see below).

Social psychologists also accept truth qua subjective personal or interpersonal experience. That is, personal experiences such as the qualitative nature of diverse emotions or spiritual awakenings may be accepted as true, yet beyond the bounds of current scientific modes of investigation or measurement techniques. Therefore, an experience may be accepted as true, insofar as an individual maintains an honest self-perception of psychological phenomena, yet outside the bounds of the accepted social psychological truth, as constructed by professional leaders in the field.

Perception

In its most general form, perception is the basic set of mental operations that brings subjective meaning to otherwise objectively meaningless stimuli. That is, while our sense of hearing can enable us to discern a wide variety of sounds, perceptual processes that lead to meaning are inherently psychological in nature and are therefore susceptible to influence from other psychological phenomena such as emotional state, cognitive complexity, motivation, and social context. In this way, although two listeners may objectively hear the same stimuli, some will perceive greater intricacy and beauty in a composition by Mozart, and this judgment will be impacted by social factors such as cultural

norms or social learning. Furthermore, these perceptual effects are often nonconscious and can often be developed through practice and training.

Time

Time is usually conceived as an objective aspect of reality, governed by regular planetary motion (e.g., the rising and setting of the sun). Different aspects of time are often implicit in social psychological theories and phenomena. For instance, theories of attitude change require that in order for persuasion to occur, in some conditions, communication messages must be delivered and elaborated on over a period of time.

Consciousness

Consciousness is often contrasted with the nonconscious and has been studied in terms of influences on affect, cognition, and behavior. John Bargh specified the “four horsemen” of automaticity – distinguishing features that together determine the nature of experience as being conscious or nonconscious: awareness, efficiency, intention, and control. Though social psychologists are far from a complete understanding of the nature of consciousness, the construct has been useful in understanding a variety of effects of interest to social psychologists. For instance, influential models of persuasion differentiate between automatic and controlled processes by which attitude change can take place: The persuasion that occurs when a person consciously thinks about an issue to decide which presidential candidate to vote for will be more durable and predictive of behavior than the persuasion that occurs when a person is nonconsciously influenced by subtle cues in a persuasive message such as attractive appearance or likeability.

Rationality/Reason

Rationality and reason are normally contrasted with more emotive or affectively based processing. Rational processes are often associated with maximizing the utility of actions to bring an individual pleasure or closer to a desired goal. Usually, such processes are considered to be conscious and cognitively based.

Mystery

Mystery describes aspects of social psychological phenomena that have not yet been thoroughly investigated in a scientific manner. That is, mystery is inherent in gaps in the field’s understanding of how the thought, feeling, and behavior of individuals are influenced by the actual, imagined, or implied presence of others. Areas such as the extent of the impact of nonconscious perception, the interaction of psychological and social forces to induce macroscopic effects such as war, and a complete understanding of the characteristics of successful romantic relationships are still being investigated by modern researchers. The collective lack of understanding of these and other effects represents the mystery that the scientific process is designed to progressively reduce.

Relevant Themes

Social psychologists also study religions as instances of social groups. Therefore, aspects of the behavior of individuals identifying with a religion will have commonalities with other social groupings such as those based on race, ethnicity, or nationality. Effects such as in-group favoritism and out-group homogeneity apply generally to members of groups, including those defined by religion.

It should also be noted that the study of religious groups in particular has been useful in understanding more general aspects of cognition and behavior. For instance, one of the most influential theories in social psychology, Leon Festinger’s theory of cognitive dissonance, was largely inspired by his study of a UFO cult in the 1950s and attempts to explain increased socialization within the group following the failed prophesy of extraterrestrial contact. The inconsistency between the prophesy and the resultant reality produced a dissonant state that group members were motivated to reduce. One mechanism of reducing this dissonance involved the seeking out of additional social support by recruiting other members into the group. Therefore, the counterintuitive finding that the group

members increasingly sought others' participation following the failure of the prophesy can be explained by the relatively simple construct of motivated dissonance reduction.

Social psychologists bring a unique perspective to the issues in the science and religion dialogue due to the fact that they incorporate both a scientific investigation of subjective psychological experience, as well as the corresponding objective social phenomena.

Description

Software engineering is a discipline that attempts to deliver fault-free software on time and within budget to meet the needs of the customer. A more formal definition from IEEE (IEEE Standards Collection: Software Engineering 1993) is as follows:

Software engineering: (1) The application of a systematic, disciplined, quantifiable approach to the development, operation, and maintenance of software, that is, the application of engineering to software. (2) The study of approaches as in (1).

There are a variety of software development life cycle (SDLC) models currently in use by professional software engineers. The first SDLC model was the Waterfall Model, but this model proved to be inflexible, as it is not conducive to changes in customer requirements or faults discovered late in the SDLC. The Waterfall Model, as originally proposed in 1970, consists of the following sequence of phases:

- Requirements (The customer's needs are determined.)
- Specification (A formal document enumerating product features and system constraints is composed.)
- Design (Architectural Design: The modules of the system are determined; Detailed Design: The data and algorithms are specified.)
- Implementation (The algorithms are translated to code.)
- Unit Testing (Individual modules are tested for correctness.)
- Integration Testing (Modules are combined and tested to check if system requirements are met.)
- Postdelivery Maintenance (Errors discovered after delivery are corrected; environment changes requiring adaptive maintenance are performed; improvements or enhancements known as perfective maintenance are implemented.)
- Retirement (The product has become obsolete or too cumbersome to maintain, so it is removed from operation.)

A more modern depiction of the Waterfall Model (see [Fig. 1](#)) contains feedback loops and often appears without testing phases. The omission of the testing phases emphasizes non-execution-based testing (Walkthroughs and Inspections) and/or execution-based testing should take place during every phase of the SDLC. Notice the terms validate and verify in the model. As originally defined by Boehm, validation is a customer-oriented activity where the developer asks the question "Are we building the *right* product?" Meanwhile, verification is a developer-oriented activity; the relevant question is "Are we building the product *right*?" It is interesting to note that even though the Waterfall Model has several shortcomings, the model or one of its adaptations is still widely used in industry (Sommerville 2007). The reason for its usage is probably due to the fact that management likes the model, because it requires developers to create a project plan with milestones and deliverables announced early in the SDLC.

The Rapid Prototyping Model was developed to counteract the shortcomings of the Waterfall

Software Engineering, Fig. 1 A modern Waterfall Model (Adapted from (Schach 2007))

Model. In particular, this SDLC model prescribes that developers first build a rapid prototype to elicit customer requirements. The prototype is often a mock-up of the proposed graphical user interface. Because the prototype is rapidly constructed without attention to design details, it should be thrown away. The phases of the Rapid Prototyping Model match those of the Waterfall Model except that prototype construction and customer feedback replace the Requirements Phase. The major advantage of the Prototyping Model over the Waterfall Model is the early customer feedback because, with feedback, the final product is more likely to satisfy the customer's requirements. However, the Prototyping Model has not proven to be successful in all cases.

Another adaptation of the Waterfall Model that clearly demonstrates the importance of testing is the V Model (see Fig. 2). In particular, the model illustrates that different types of test cases should be written in the early phases of the SDLC model as opposed to after implementation. For example, acceptance test cases should be written

during requirements elicitation. Similarly, integration tests can be written during Architectural or Preliminary Design, and unit tests are easily constructed when performing Detailed Design.

Another important SDLC model is the Spiral Model developed by Barry Boehm in 1988 (Boehm 1988). The illustration of the Spiral Model is perhaps the most complex of all SDLC models (e.g., Waterfall, Rapid Prototyping, ► [Evolutionary Prototyping](#)) of its time. The Spiral Model is especially important, because it was the first SDLC model to promote ► [risk analysis](#). A simplified way of thinking about the model is to consider it as the Waterfall Model with each phase preceded by risk analysis (Schach 2007). However, the actual model contains a spiral drawn over four quadrants, and each quadrant contains a guideline for development. In particular, software developers should first determine project objectives and consider alternatives; second, they should evaluate the alternatives and resolve the risks, if possible; next, they should perform the activities associated with the phase in question, including verification; and finally, they should plan for the next phase. The major tenet of this model is software developers should perform risk analysis, and if the risks are too great, a project should be abandoned.

In today's world, the majority of software developers support an incremental, iterative approach to software development. That is, in order to better fulfill the customer's needs, software is constructed in increments with customer feedback at the completion of each increment. However, even when incremental development is employed, there are two widely differing schools of thought on how to best produce a software product. The conflicting models and associated guidelines are known as the disciplined or plan-driven approaches versus the agile methodologies (Boehm and Turner 2004).

A comprehensive plan-driven method is the Rational Unified Process (RUP) (Jacobson et al. 1999), which was developed by Booch, Rumbaugh, and Jacobson. Unlike other software development life cycle models, the RUP model contains both a vertical axis and a horizontal axis

Software Engineering,
Fig. 2 The V Model

(see Fig. 3). The vertical axis specifies the disciplines (formerly known as workflows), which are similar to the phases of the Waterfall Model, whereas the horizontal axis denotes the actual phases of RUP. There are five major disciplines: Business Modeling, Requirements, Design, Implementation, and Testing. Other disciplines include Deployment, Configuration and Change Management, Project Management, and the Environment. At the same time, there are four phases: Inception, Elaboration, Construction, and Transition. During any one phase, developers may perform activities associated with multiple disciplines, although one or more disciplines usually predominate a phase. (Fig. 3 depicts a typical project; different projects would have different graphs.) The disciplines precisely describe the activities that software developers undertake when building software applications. In other words, developers follow a sequence of steps to implement a deliverable, but often iterate the steps in order to improve the documentation, correct errors, or adapt to changing requirements. In contrast, the phases of RUP correspond to management goals such as well-defined

schedules with deliverable dates for documentation such as the Vision Statement, the Software Requirements Specification (SRS), the Design Document, and Test Cases. Note: Nowadays this model is usually referred to as simply the Unified Process (UP).

Another thorough plan-driven method is the Team Software Process (TSP) (Humphrey 2000), which was developed by Watts Humphrey at the Software Engineering Institute (SEI). This method prescribes activities for individuals on a software development team based on their roles, and is meant to be used with Humphrey's earlier Personal Software Process (PSP). Note that PSP guidelines were written by Humphrey in response to companies being unable to reach acceptable levels of "goodness" in their processes as outlined in the original Capability Maturity Model (CMM). (See below for a description of CMM.)

An important skill for software engineers is the ability to model software systems. A modeling notation associated with RUP is the Unified Modeling Language (UML), which has become an industry standard. There are seven

Software Engineering,
Fig. 3 Unified process

major diagrams of UML: the Use Case Diagram, the Class Diagram, Interaction Diagrams (the Sequence Diagram and the Communication Diagram, formerly known as the Collaboration Diagram), the Statechart Diagram, the Activity Diagram, the Component Diagram, and the Deployment Diagram. Most tools supporting UML allow users to draw Use Case Diagrams, which specify the functionality of the system from the user's viewpoint; Class Diagrams, which denote the attributes and methods of each class and also illustrate the relationships and dependencies among classes; and Sequence Diagrams, which denote the time-ordering of messages between the objects of a software system. Although UML is normally associated with RUP, software engineers employing any other method may choose to model their software using one or more of the UML diagrams. For those applying agile methods, the Class Model and Sequence Diagrams would be the most likely choices.

The philosophy behind agile methods is best stated in the Agile Manifesto of 2001 (Beck et. al 2001).

- *Individuals and interactions* over processes and tools

- *Working software* over comprehensive documentation
- *Customer collaboration* over contract negotiation
- *Responding to change* over following a plan

The Manifesto itself is often misunderstood. Sometimes software developers will state that they are following an agile process, because they do not bother with documentation. However, all agile methods require documentation; the documentation produced is just different when compared to the deliverables of more traditional, plan-driven methods. Perhaps a better way to state the agile enthusiasts' point of view is the following: The most important objective of a software development team is to deliver a working product that meets the customer's needs. In other words, the developers should not become bogged down in documentation or become overly concerned with adopting the newest process or tool. Their goals can best be met by interacting with the customer throughout the project and having the farsightedness to change an infeasible plan.

There are several agile methods, but the most popular are Scrum (Schwaber and Beedle 2001) and Extreme Programming (XP) (Beck 2004).

As stated above, in UML, the functionality of a software system is expressed by the developer by drawing use case diagrams and a corresponding description for each use case. In contrast, in agile methods, customers record their requirements as user stories on index cards. An important characteristic of agile methods is the time boxing associated with incremental development. In particular, a software development team works a specified time period before displaying or delivering an increment to the customer. In Scrum, a typical increment, also known as a sprint, is about a month, whereas in XP, the time period is usually about 2 weeks. With both methods, customers prioritize the requirements, thereby allowing them to view or interact with more important features earlier in the SDLC. A distinctive characteristic of Scrum is the Daily Scrum, a meeting lasting about 15 min in which each team member describes his or her progress, problems, and plans for the day. Extreme Programming is more disciplined than Scrum, as its developers prescribe 13 practices. Below, we describe two distinguishing features: pair programming and test-driven development.

In pair programming, one developer acts as the pilot or driver for the code, while the other member serves as the copilot or observer. The pilot controls the keyboard and is responsible for algorithm creation; in her role, she is said to have “tunnel vision.” At the same time, the copilot looks for both syntax errors and logical faults; we also say that she is in charge of the “big picture,” or, in other words, how the code being implemented fits into the overall product. Another one of the copilot’s duties is to suggest when roles should alternate, as one developer may become tired, often with an associated degradation in performance. In agile teams, it is also recommended that individuals work with different partners occasionally, because pairs may become so accustomed to working together that the benefit of automatic reviewing of the algorithm and associated code is lost.

There are two testing activities associated with test-driven development: acceptance testing and unit testing. In acceptance testing, customers (perhaps with the help of developers) compose

their own test cases. Note each test case represents a particular scenario, and the customer typically uses a tool with tables in which he or she enters various values representing input data, along with the desired results or output. Meanwhile, unit testing in XP is called test-first development, because developers write their test cases in code before any production code is written. Naturally, when the test cases are first executed, they fail. Then, the developers’ strategy is to write “just enough code” for the test case to pass. Issues such as efficiency, readability, maintainability, and so forth are addressed later when the code is refactored.

It is important to note that there is really no best software development process (SDLC model plus associated guidelines) for all types of software applications. A process model should be selected based on the application domain including the degree to which requirements change, the size of the development team and the experience of its members, and the culture of the development organization (Boehm and Turner 2004). In reality, there are times when a combination of the agile and plan-driven methods is actually the best approach to implement a software product.

When developing safety-critical systems, a plan-driven approach is usually more desirable. A safety-critical system is a software system that may result in injury, loss of life, or damage to the environment. An example of a safety-critical system is the software monitoring a nuclear power plant. Furthermore, formal methods, which are mathematically based techniques, may be employed. There are two major categories of formal specification languages: algebraic and model oriented. With an algebraic specification language, a system is first described in terms of its operations by providing a signature (the input and output types, known as sorts) for each operation. Next a collection of axioms describes the relationships of the operations. In contrast, with a model-oriented specification language, the developer builds a model of the system using mathematical constructs such as sets and functions. Another consideration when building safety-critical systems is verification techniques, which may include proofs of correctness.

A related issue to process models is team organization. Just as there are widely disparate software development paradigms, team models exist at both ends of the spectrum. The two most widely cited team models are the Chief Programmer and the Democratic Team, but there are many other models as well. Note that companies using a plan-driven method will usually have a hierarchical team structure, whereas agile teams prefer the Democratic model.

In the Chief Programmer Model, each team member has a role to perform with associated duties. For example, the Chief Programmer is both the team leader and the team manager. As the leader, the Chief Programmer constructs the system architecture, and is ultimately responsible for every line of code. There is also a Backup Programmer, who has the same qualifications as the Chief Programmer, and is capable of replacing the Chief Programmer if necessary. A person responsible for system documentation called the Secretary and several general programmers comprise the remainder of the team. The advantages of this model are specialization and the limited number of communication paths (due to a hierarchy in interacting with the Chief Programmer). The major shortcoming of the model is finding personnel that can fit each of the roles, especially two people (Chief Programmer and Backup Programmer) who are excellent managers as well as established programmers.

Meanwhile, the Democratic Team or “ego-less team” has no designated leader. Rather, this team structure often arises in a research environment, where all team members respect the knowledge that each individual brings to the table. In a Democratic Team, the code belongs to the whole team. Because there is no “finger pointing” when errors are discovered, Democratic Teams are said to be better at locating faults and often produce higher quality code. The disadvantage of the model is the number of communication paths, because as the number of team members increases, the number of communication paths produces a ► [combinatorial explosion](#).

In today’s global economy, team members are not necessarily colocated, rather they may have

offices in different buildings, different cities, different countries, or even different continents.

Distributed teams offer specific challenges for software developers and management. For example, team members may have different technical backgrounds, come from dissimilar cultures, work in separate time zones, just to name a few concerns. Organizations are currently experimenting with modified team structures (including those with an agile leaning as reported in the 2008 Agile Alliance Conference).

Another phenomenon related to team structure is open source code. Nowadays, many software products are developed as open source, meaning that they are freely available on the World Wide Web. Usually there is a cadre of developers, but these primary developers allow others to suggest improvements and/or alter their code.

As mentioned earlier, CMM, which became S-CMM, was a process improvement and assessment model for organizations. Founded at the Software Engineering Institute in 1986, CMM described five levels of “goodness” and corresponding key process areas that an organization should follow, if it wanted to improve its process. The highest rating that a company could achieve was Level 5, which included two important imperatives: (1) a company should have a continual process improvement strategy in place and (2) a company should encourage innovative ideas and technologies. When a company’s process was formally evaluated, it received a single rating. For example, a company might be following a key process area in Level 4 but only receive a Level 2 ranking. The reason for this discrepancy was the fact that all key process areas of a particular level and all levels below must be exercised to receive the higher rating.

In 2001, the Software Engineering Institute compiled the Capability Maturity Model Integrated (CMMI). This process improvement model has several advantages over its predecessor Software Capability Model (S-CMM.) First, it combines several different capability models including the Software Capability Model, the Systems Engineering Capability Model, and the People Capability Model into a single framework. Furthermore, with respect to software, the

CMMI actually has two models: the staged CMMI and the continuous CMMI.

For companies accustomed to applying S-CMM, the staged CMMI is especially attractive. Like S-CMM, a company must practice all key process areas at a particular level to achieve the associated ranking, and ranks range from 1 (Initial) to 5 (Optimizing). However, if a company is more interested in assessing specific key process areas, the continuous model may be more appealing. In particular, the continuous model specifies goals to achieve along with desired practices. Furthermore, when using the continuous model, an organization receives a collection of ratings corresponding to the key process areas of interest. For example, a company could work on the six key process areas in the category of engineering and receive a ranking for each. If using the staged model, only a single ranking for the entire organization would be given.

Self-identification

Science

The term “software engineering” arose in 1967 as a result of a NATO study group, and the first conference devoted to the topic was held the following year in Germany. The goal of the attending members was to prescribe a more disciplined approach to the development of software applications. In other words, the motivation for the term was practitioners and academicians should pattern software development after the older, more established subdisciplines of engineering. Although a laudable goal, software engineering is actually very different from traditional engineering. To illustrate this point, let us compare software engineering to the older engineering subdiscipline civil engineering. When building a bridge, a civil engineer can build a model before constructing the final product, whereas software is invisible. Furthermore, the civil engineer has a foundation of knowledge that was built on “thousands of years of experience” compared to a mere 40 years for the field of software engineering. Similarly, the public’s expectations are different when comparing

software to a bridge. For example, when using software applications such as operating systems or word processors, oftentimes the software will fail, and the customer has come to accept these defects as necessary evils of computer systems. However, if a bridge collapses, the public is much less forgiving. Another difference between bridge-building and software construction is the type of mathematics involved. Traditional engineers must use calculus, which considers continuous functions, whereas a software engineer applies the theories of discrete mathematics. In other words, a software engineer must consider all of the system states, which are discrete, that a software application may occupy. However, the paradox is there is no way for a developer to determine “all” the states or the ways that a computer application may be used; because, when computer applications are successful, customers ask for additional enhancements (perfective maintenance) or use the system in unexpected ways resulting in software failures requiring corrective maintenance.

Characteristics

This question was best answered by Frederick Brooks in his definitive essay “No Silver Bullet.” That is, four characteristics of software engineering distinguish the discipline from the other sciences. Brooks describes each of these features in the following order: complexity, conformity, changeability, and invisibility. See the section “[Science](#)” for a discussion of complexity (number of discrete states in a system). Conformity means that software must comply with the requirements of a workplace or customer. These requirements may not be the most natural way to approach the problem making the developer’s job more difficult than necessary. Changeability is also discussed under section “[Science](#)” in that satisfied customers often request additional features when they like a product. Furthermore, as the world, economy, and so forth change, software needs to be modified (adaptive maintenance). The invisibility of software compared to physical models in other sciences is self-evident.

Relevance to Science and Religion

For the majority of software engineers, there is little interest in the area of “Science and Religion.” However, software engineers are interested in improving the lives of individuals. As an example, let us consider software used in the field of medicine. We all have heard of cases where a doctor predicts a patient will not recover or will only live for a limited amount of time, but the patient exceeds the doctor’s expectations; oftentimes, there is no medical explanation for this occurrence. Those who believe in religion might say that the patient’s experience is an “act of God.” Software engineers build systems that help doctors to better predict the illnesses (e.g., cancer, dementia, etc.) that plague mankind. Such applications are known as diagnostic systems.

Sources of Authority

Conference and journal articles are one major source of authority for this discipline/subdiscipline. The major conference is the *International Conference on Software Engineering (ICSE)*, and the major journals are *IEEE Transactions on Software Engineering* and *ACM Transactions on Software Engineering and Methodology*. All of the published articles in these sources are peer reviewed. Two other sources of authority are the Special Interest Group on Software Engineering (SIGSOFT), which is sponsored by ACM, and the *Guide to Software Engineering Body of Knowledge* (also known as SWEBOK), which is sponsored by the IEEE Computer Society. There are also many IEEE Standards publications that target specific subareas of software engineering. Finally, another source of authority is the Software Engineering Institute (SEI), which originated in 1984 at the request of the U.S. Department of Defense. SEI publishes several white papers each year describing research conducted at the Institute. Note: This is not an exhaustive list of sources. For example, there are several other major conferences devoted to software engineering

(e.g., *Fundamental Approaches to Software Engineering (FASE)*), as well as many well-respected conferences targeting subareas of the discipline (e.g., *International Conference on Requirements Engineering (RE)*).

Ethical Principles

The Software Engineering Code of Ethics (and Professional Practice) is comprised of a short version and a long version. The short version prescribes eight principles to which a software engineer should aspire, whereas the long version outlines specific examples for more guidance. In the discussion below, the principles are paraphrased, but the associated categories remain unchanged. Note: The categories are listed in the order of importance. In other words, if there is a conflict of interests, the principle with the lower number has priority.

1. Public: The foremost principle is software engineers must consider the interests of the public before all other concerns.
2. Client and Employer: The interests of the client and the employer should be considered when developing software.
3. Product: The original product and any modifications to the product after its initial delivery should meet the highest professional standards possible.
4. Judgment: Software engineers should adhere to both moral and ethical principles when making decisions in their daily jobs.
5. Management: Managers should foster an environment where both managers and engineers abide by the ethical principles when developing and maintaining software.
6. Profession: Software engineers need to demonstrate their ethical principles when dealing with the public. Furthermore, they should advance the knowledge of the public when they have opportunities to do so.
7. Colleagues: Software engineers should help their colleagues and give credit where due.
8. Self: Software engineers should continue to learn new techniques for software development, as information technology is a rapidly

changing field. Furthermore, software engineers should adhere to moral principles in their professional lives.

Key Values

In the Code of Software Engineering Ethics and Professional Practice, it states that software engineers should commit themselves to making the discipline a respected profession. Furthermore, they should always strive to promote the health, safety, and welfare of the public.

Conceptualization

Nature/World

Software engineers consider nature as the items in the world that are not necessarily associated with human beings. When developing applications, software engineers must consider the effects on the environment.

Human Being

The discipline of software engineering considers a human being to be a member of the human race or, in other words, a person (living or dead). The Software Engineering Code of Ethics states that a software engineer's primary responsibility is to the public. In other words, if there is a conflict of interests, the concerns of other human beings should be foremost.

Life and Death

Life is the beginning of existence for members of the plant or animal kingdoms, whereas death is the ending of this existence. However, the discipline of software engineering considers the concept of life as the steps in the development of a software application. (See the discussion of software development life cycle models in section "[Description](#)").

Reality

Reality refers to living or nonliving items that actually exist. Software engineers may build "virtual reality" systems, which are imaginary

worlds simulated by computers. For example, users might like to imagine that they are playing particular sports or going to exotic vacation spots.

Knowledge

Knowledge is information gained through study and reasoning. The management of knowledge and knowledge engineering are both important to the field of software engineering. For example, knowledge management is a necessary requirement when building an expert system.

Truth

Truth is a fact that has been proven or, in other words, the opposite of a falsehood. Software engineers have a responsibility to educate the public about technology. A concern is some computer users are naïve or uneducated in basic computer literacy. For example, naïve individuals may believe that all output from a computer application is correct or that all information on the Internet is true.

Perception

Perception is an individual's interpretation of a situation or a concept by using one of the five senses. A common perception among the public is a software engineer spends most of his/her time programming. However, the majority of software nowadays is developed in teams, where software engineers meet regularly with the customer and report to management. In other words, the job of software engineer requires excellent communication skills, and the activities in a typical day involve much more than programming (see discussion under section "[Description](#)").

Time

Software engineers define time as the duration of a period, measured in minutes, hours, days, and so forth, for an activity to be completed. They are especially interested in delivering software "on time." Like computer scientists, in general, software engineers must also consider the "run-time" of the algorithms that they use to solve problems.

Consciousness

Consciousness is an awareness of a problem or concept.

Rationality/Reason

Rationality is the ability to make the optimal choice, whereas reason is the action of considering alternatives. This concept is of major importance to software engineers. In fact, if one were asked to describe the requirements for the job of software engineer, the ability to reason might appear first. Two examples follow. First, when implementing a program, a software engineer must consider the trade-offs between how data is stored (a space issue) versus efficiency (runtime). Similarly, a software engineer must deliberate the price that a customer is willing to pay for a product versus the amount of time that it will take to implement the desired features. As a point in question, some features of a system might have to be implemented in a future release due to customer's time and cost constraints.

Mystery

A mystery is an occurrence or phenomenon with no logical explanation.

Relevant Themes

There are now several universities that offer degrees in software engineering. When compared to computer science degrees, software engineering degrees are more application oriented, whereas computer science degrees are more theoretical in nature.

In 2004, the Software Engineering volume of *Computing Curricula* designated ten knowledge areas: Computing Essentials, Mathematical and Engineering Fundamentals, Professional Practice, Software Modeling & Analysis, Software Design, Software Verification & Validation, Software Evolution, Software Process, Software Quality, and Software Management. Some of the topics in the knowledge areas coexist with topics in the Computer Science or Computing Engineering volumes of *Computing Curricula*.

Soul

Paul L. Allen

Department of Theological Studies, Concordia University, Montreal, QC, Canada

Related Terms

Dualism; Psyche; Self; Spirit

The idea of the human soul defines what most people think of as the inner being or core principle of an individual person. The anthropogeny contained in the *Atrahasis* poem of ancient Mesopotamia contains initial hints of ensoulment, since by mixing the flesh and blood of a god that the other gods have killed with clay, a new creature is formed. The soul is related conceptually to the Hebrew word *nepheš* (נֶפֶשׁ) in the Hebrew Bible which refers to a living being which breathes. A living being is that which breathes, an effect of God's breathing life into Adam through his nostrils (Gen. 2:7). A dualism is potentially implied between the spiritual living being and the physical dust from which the human is created. Prior to the development of a belief in the resurrection of the body in Judaism and the Christian church, the soul in the Hebrew Bible goes to *She ol* after death. In the Hebrew Bible, the soul of a living being refers to an aspect of a person, the seat of one's appetites, the self and even mental processes, including the will.

In Hellenistic culture initially, the soul was a univocal means for expressing how a living organism lives and mentally functions. A conceptual separation of the soul from the body became formalized through the use of the different words for spirit (*pneuma*), body (*sōma*),

and soul (*psuchē*). Plato's idea of a disembodied post-mortem life, of immortality, develops earlier ideas from the Homeric age. Plato's dualism between physical and ideal realities signifies the identity of personhood with a non-visible soul. He was opposed by Aristotle, who held out for the existence of souls as essential operating principles for all living things, including plants and animals (Aristotle, 1961).

Christian belief in the human soul is attested by the numerous mentions of *psuchē* in the New Testament. Related to the Greek verb *psuchēin* "to breathe," this word refers to a natural sense of self, in continuity with the Hebrew word *nepheš*. In contrast, *pneuma* is associated with the equally less physical Hebrew word *ruah*. This spirit, in contrast with ordinary human soul, is associated with the being of God, a predecessor to the development of the Christian doctrine of the trinity. Yet, Paul is less precise in employing the term *pneuma*, as, for instance, in 2 Cor. 2:13, which suggests the notion of soul. And, the New Testament generally assumes a body-spirit unity rather than a notion of human persons who "have" either a soul or body, despite Paul's account of struggle between the flesh and the spirit.

In Islam, the word *nafs* (etymologically similar to the Hebrew *nepheš*) means soul and is distinguished in the Qur'an from God's spirit or *ruh*, which is breathed into humans at their creation. Al-Kindī (d. c. 870) articulates an Islamic philosophical notion of the soul in neoplatonic terms, while Ibn Sīnā (or Avicenna, d. 1037) is the most influential exponent of an Islamic understanding of individual immortality of the soul. Sufi interpreters of the soul emphasize its role in the mystical experience of God, while its metaphysical status is contested among Sufi philosophers. And, among Indian religions, the soul is an accepted concept that marks off the living from the dead.

Historically, and especially in the science-religion dialogue, accounts of the soul are related to accounts of mind. Particularly since philosopher René Descartes defended a causal interaction between two separate entities, mind and body, the soul has come to be associated with dualism, which postulates the separate, mutual causation of two kinds of phenomena: spatial physical

objects and nonspatial mental events. For Descartes, nevertheless, the soul was postulated as located in the pineal gland, where he speculated that all thoughts are formed (Descartes, 1897).

A subtle mind-body dualism is proposed by Thomas Aquinas, who sees the soul in terms of an Aristotelian outlook, where the soul is the formal, not the efficient, cause of thought and bodily movement. This is the most well-known form ofhylomorphism, in which the substance of the person is understood as a composite of matter and form. The human person is “not a soul only but rather a composite of soul and body” (Aquinas 1964–1973: I, q75, a4). While Aquinas’ and Descartes’ accounts of the soul share a substance metaphysics, the semantic thrust of Aquinas’ understanding of substance is conducive to the idea that mind can emerge from the physical world. Hence, current defenders of the idea of the soul are more likely to rely upon a Thomist metaphysic than a Cartesian metaphysic. Prominent exponents of a substantial soul include the philosophers Karl Popper, John Eccles, and, earlier in the twentieth century, neurophysiologist Wilder Penfield. Contemporary Thomists, such as Fergus Kerr and Alasdair MacIntyre, argue for the retention of a broadly Aristotelian notion of human personhood in terms of rational animals, as opposed to the idea of humans as essentially thinking beings.

Some contemporary thinkers expound an “emergent dualism,” in which the soul is the organizing principle within a network of complex rational and affective operations that potentially orient the reception of God’s grace. For W.G. Leibniz (1646–1716), the soul plays a role in his metaphysical view which mediates two famously opposed eighteenth century dualist portraits of consciousness: those of Descartes’ picture of mind-body interaction and Malebranche’s suggestion of a miraculous cause for mental events. Leibniz sees the concept of the soul as important for the “primitive unities” of bodies, which are otherwise aggregates of non-unified substances. Jean (John) Calvin discusses the soul in the *Institutes* and affirms it in continuity with medieval thought, as, for example, when he claims “man consists of

a body and a soul; meaning by soul, an immortal though created essence” (Calvin 1960: I,15).

In the contemporary period, materialists deny the existence of the soul due to their belief that consciousness is entirely physical in nature. This denial takes a number of forms, beginning with British philosopher Gilbert Ryle’s description of Descartes’ dualism as that of a “ghost in the machine.” Another criticism materialists make is that the soul is simply based upon a commonsense view of mind constituted by an invalid “folk psychology.” So, on the materialist view, the notion of the soul is unable to illumine any problem of consciousness. Cognitive scientist Steven Pinker claims that the mind “is what the brain does,” a functionalism that stresses the role of physical causal relations in making up mental states, thus disallowing any nonbiological elements in cognition, emotion, or higher forms of reason. Daniel Dennett adopts a similar skepticism toward the mind and, by extension of the soul, in his well-known eliminativism: philosophical problems arising from consciousness are to be eliminated from existence because they are problems based on nonscientific, unanalyzable, first-person accounts of experience (Dennett, 1992).

Opposed to materialism is a range of philosophers who stress a number of elements, especially those of thought and intentionality. Richard Swinburne’s composite dualism posits that mental properties are ascribed to the soul while physical properties are ascribed to the body (Swinburne, 1997). Property dualists hold, contrary to Descartes, that there is only one material substance, yet there are two kinds of properties, physical and nonphysical. This position is sometimes called “dual-aspect monism.” William Hasker holds that individuals emerge alongside the properties for consciousness in bodies. His position is called “emergent” dualism wherein the mind is a “soul field” analogous to a magnetic field’s relationship to a magnet (Hasker, 1999). For Hasker, both humans and animals possess souls. Nancey Murphy and others adopt a “nonreductive physicalism,” which stresses a definition of supervenience, in which mental events supervene by means of informational feedback loops upon neural

processes, thus leading to “downward causation” of the mental on the neuronal. Yet, for Murphy, the soul is ultimately an unnecessary concept for Christian belief. And, in a similar vein, Kevin Corcoran advances a “constitution” view wherein the human person is constituted by bodies but not identical with bodies. Less scholarly contemporaries provide the soul with a looser psychological, phenomenological, or spiritual meaning. Examples of thinkers in this genre include James Hillman, Gerald May, and Ken Wilber.

Introduction

What is space? By this we do not necessarily mean outer space – the cosmos. We are talking of space in general. The obvious answer seems to be “nothing.” If there are no objects in a particular region of space, we speak of it as being empty space – which seems to imply nothingness. And yet that is not how the modern physicist views it.

The Expansion of Space

The sun is a star. The stars are gathered into great swirling whirlpools called galaxies. Galaxies in their turn form clusters of galaxies. When we view distant galaxy clusters we find that they are all retreating from each other. The universe is expanding. This is in the aftermath of

the Big Bang which is believed to mark the creation of the universe. But the Big Bang was not an explosion like other explosions. The galaxy clusters are not receding from us by moving through space; it is space itself that is expanding and carrying the clusters along with it. The situation is similar to inflating a rubber balloon on which 5p coins have been glued. The coins separate not because they are sliding over the rubber into regions where previously there had been no coins. They are separating because the rubber in between them is expanding. So it is with space. The clusters are being carried along on a tide of expanding space. This is our first indication that space is hardly to be regarded as nothing!

The Creation of Space

At the instant of the Big Bang, all the contents of the universe were at a point. But not just the contents, but space itself. A point has no volume. For this reason it is believed that the Big Bang saw not only the creation of the contents of the universe, but also the creation of space.

The Curvature of Space

A space station moves in orbit about the earth. Why? Because of the force of gravity exerted on it by the earth. That, at least, is how one conventionally describes the situation. However, there is something very odd about the gravitational force. We can see that by considering an astronaut

stepping outside the space station and floating in orbit alongside it. Both the astronaut and the station are essentially traveling in the same path. But the astronaut is much lighter than the spacecraft, so it takes less force to keep her on course than it does the craft. Thus gravity has to pull less strongly on her than on the craft. Gravity somehow seems to know exactly how hard to pull on objects to make their motions the same. How does it know? And in any case, *why* would it want to keep both the craft and the astronaut on the same path?

The answer from relativity theory is to do away entirely with the concept of gravitational forces. Instead it holds that a better way of looking at things is to say that what the Earth is doing is not exerting a force on the objects orbiting it, but instead it is curving, or warping, the surrounding space. As a result of this distortion of space, anything passing through the affected region no longer travels in a straight line. Instead it follows a curved trajectory. The spacecraft and the astronaut follow the same path because that is the *natural* path for *any* object to follow if they start off from the same point with the same velocity. The natural path is not a straight line – a straight line requiring a force to convert it into an orbit. It is as though the Earth has caused a dimple in space – much as a ball bearing would if placed on a stretched rubber sheet (see Fig. 1). A second ball rolling across the sheet – say, a light table tennis ball – would follow a curved path because of the curvature of the sheet. It might even find itself captured into an “orbit” repeatedly circling the ball bearing. So, the Earth causes a dimple in three-dimensional

Space, Fig. 1 The Earth causes the surrounding space to curve, this curvature being responsible for spacecraft and spacewalkers following curved orbits

space, and the Sun an even more pronounced dimple such that the Earth finds itself describing an orbit around it.

This way of viewing gravity – which we owe to Einstein’s general theory of relativity – comes up with more accurate descriptions of nature than Newton’s ideas based on an inverse square law of gravitational forces – and so is to be preferred. Thus we find space is something that can be curved.

Space and Quantum Theory

According to quantum theory, so-called empty space is not empty at all. Instead it is a seething crowd of subatomic particles popping into and out of existence. It is a manifestation of the basic uncertainty that afflicts everything going on at the subatomic level.

How can particles, which were not there before, suddenly come into existence? Did we not learn at school that “matter can neither be created nor destroyed”? The simple answer is that this statement is not true. According to relativity theory, matter is just another form of energy – much like the others: kinetic energy, the energy of the Sun’s rays, heat energy, etc. There is a law called the law of conservation of energy. It maintains that whatever energy you have at the beginning (in all its forms) will be the amount of energy you will have at the end. From this it would appear that if one starts off with the zero energy of empty space, one cannot create particles in it – the particles being a form of energy. However, that is not the whole story. This is where Heisenberg’s uncertainty principle comes in. While it agrees that the law of conservation of energy must hold in the long term, averaged over a period of time, there can be minute fluctuations over shorter times. A physical system can “borrow” energy, provided it pays it back within the brief time specified by the principle. It is similar to a short-term loan to cover a firm’s temporary cash flow problem, rather than an extended mortgage for a house purchase. The reason these energy fluctuations are not obvious in normal everyday life is that they are so transient. They are too fleeting to notice.

But on the subatomic scale, the energy fluctuations can be significant. All of atomic and subatomic physics must take account of quantum uncertainties. And in the present context, when thinking of the nature of space, we must allow for subatomic particles to be popping into and out of existence thanks to this fundamental uncertainty. We do not actually *see* these particles; they disappear again much too quickly. For this reason they are called *virtual particles*. They are expected to be formed in pairs rather than singly: particle/antiparticle pairs. Antiparticles have the same mass as their particle, but opposite values for other properties, like for example, electric charge. Thus, an electron has negative electric charge, whereas the antielectron – called a *positron* – has positive charge. The proton – one of the constituents of atomic nuclei – has positive electric charge, whereas the antiproton has negative charge. The creation of a virtual particle/antiparticle pair will therefore not violate other physical laws such as the law of conservation of electric charge which has to be obeyed rigorously.

It is in this way the physicist has further reason to consider so-called empty space to be not empty at all.

Dark Energy

All this quantum activity is expected to give rise to an overall average energy. This energy – the energy characteristic of empty space – is called *dark energy*. Dark energy accounts for 70% of all the energy in the cosmos; it outstrips that of the matter we see. Though we never see the virtual activity causing the dark energy, the dark energy is expected to be there. Indeed, Einstein himself was aware, from his equations of general relativity, that empty space could have an energy density itself – an energy density that would be the same everywhere. Though the energy cannot be seen directly in the form of virtual particles, it is expected to produce detectable effects. It should give rise to an expansion – moreover, one that is accelerating. In other words, unlike gravity which attracts, dark energy produces a repulsion.

Until recently it was thought that, although the universe is expanding, with the galaxy clusters separating to greater and greater distances, they will be slowing down because of the mutual gravitational attraction between them. But in 1998 it was discovered that the distant galaxy clusters, far from slowing down, were actually accelerating away from us. It is now believed that at an earlier stage of expansion there probably was indeed a slow down due to gravity. But operating against this attraction was the repulsion of dark energy. With the expansion of the universe being due to an expansion of space, there was ever more space being created, and with it more and more dark energy to go with the new space. It is the enhanced repulsion due to the increasing amount of dark energy that has now led to us passing over into a phase of the universe's expansion where dark energy has at last won the day in its battle against the gravitational attraction, and the clusters are no longer slowing down but accelerating away from us. And all this is due to the action of so-called empty space!

Holes in Space

We mentioned just now how particles had antiparticles. The existence of antiparticles was actually predicted by Paul Dirac long before they were experimentally found. Here we are talking about *real* antiparticles as opposed to the virtual ones we have so far dealt with. These are produced at particle accelerators where subatomic particles like electrons and protons are accelerated to high energy and then undergo violent collisions with the transformation of energy of motion into energy in the form of new matter – new subatomic particles.

Dirac was engaged in seeking an expression for the energy of an electron, taking into account the new insights that had become available through Einstein's theory of relativity. The details do not concern us. Suffice to know that the last step in the derivation involved taking a square root. Now, as is well known, two solutions arise whenever one takes a square root – a positive solution and a negative solution.

For example, the square root of 4 is either +2 or –2. Thus Dirac found that the mathematical solution to his problem yielded a positive value for the energy of the electron and a negative one. The first solution correctly described the behavior of the electron. But what about the negative solution? In this sort of situation it is customary to discard the negative value as being “nonphysical” – a quirk of the mathematics having no practical significance. After all, if an electron did have a negative energy it would mean that its locked up energy, that is, its mass, would be negative. That would imply a particle such that when you pushed on it, it would come toward you, and when you pulled on it, it would move away! Clearly we know of no such behavior. So the sensible thing would simply have been to ignore the negative solution as just a mathematical oddity.

Dirac, however, thought differently. By an astonishing piece of lateral thinking, he suggested that the reason we never saw negative mass electrons was not because they did not exist. On the contrary, we did not see them because there were so many of them! They were everywhere – literally *everywhere*. They filled up the whole of space – even the space between the nucleus and the electrons of an atom. Negative energy electrons formed a continuum – a perfect continuum – and a feature of a perfect continuum is that it is undetectable; it cannot be observed. To be able to observe something, a chair, say, it must be characterized by being at a particular location in space. You need to be able to point to it and say “I am talking about that; I am not talking about anything else in the room.” But in the case of the continuum of negative energy electrons, where does one point? Everywhere – and nowhere in particular.

Dirac did not let this difficulty put him off. He hit on a way that might disturb the continuum. He envisaged a particle, or a packet of light energy (called a *photon*) moving through space and hitting one of these unseen negative energy electrons. In doing so, it could be that the impact was so great, and the consequent energy transfer so significant, that the negative energy electron acquires sufficient energy to convert its negative

mass into a normal positive mass. This being the case, the electron would no longer be part of the continuum of negative energy electrons, and would thus suddenly become visible; it would appear to have popped into existence from nowhere. Not only that, it would leave behind a “hole” in the continuum. What would that look like? It would be a loss of a negative mass – which is equivalent to a gain of positive mass. So the “hole” would appear to be a particle with the normal mass of an electron. What else? The original negative mass electron would have had a negative charge like any other electron. But now we have the loss of a negative charge – which is equivalent to the gaining of a positive charge. So the “hole” would show up as a positively charged particle with the same mass as the electron – the antielectron, or *positron*. In summary, such a collision would give rise to a pair of particles – an electron and a positron. And indeed, this is exactly what is observed. Particle-antiparticle pair production is now a well-established phenomenon.

This then is another indication that empty space is not to be regarded as simply nothing. It is packed with negative mass electrons – and also with the negative mass versions of many other fundamental particles described by Dirac’s equation, such as the proton and neutron.

Or is it? Although it is true that the negative energy continuum was the route by which Dirac came to his prediction of the existence of antiparticles and how they might be produced – a discovery for which he was awarded the Nobel Prize – the question arises as to whether this actually is a true description of reality. Opinion is divided. Some physicists will have nothing to do with the continuum idea. The fact that Dirac correctly predicted the existence of antiparticles by a somewhat quirky line of reasoning does not necessarily mean that this is the correct way of looking at things.

The Dimensionality of Space

A popular physics theory at the present time is string theory. This is based on the idea that the

fundamental particles, such as the electron, are not point-like particles as hitherto thought, but tiny vibrating strings. It is the different modes of vibration that confer on the particle its various properties such as mass and electric charge. One of the features of the theory is that in order to accommodate all the required properties, the vibrations must be in 10 or 11 spatial dimensions. But we only know of three. This gives rise to the idea that the additional dimensions might be curled up so tiny we cannot see them, that is, at each point in three-dimensional space there are 7–8 curled up dimensions. Whether this is so or not has still to be resolved.

A Smallest Unit of Space?

We are accustomed to thinking of it as being divisible into ever smaller distances: kilometers, meters, centimeters, millimeters, nanometers, and so on. But does that go on indefinitely? Is there no limit to how small a division of space can go? Or do we eventually get to a basic unit of space that is no longer divisible?

At present we have two great physical theories: quantum theory and general relativity. The eventual aim is to reconcile these two into a combined theory of quantum gravity. Such a theory is bound to depend very heavily on three fundamental constants: (1) the gravitational constant, G , governing the strength of gravity in both Newton’s theory of gravity and Einstein’s general theory of relativity; (2) Planck’s constant, h , governing the size of quantum fluctuations, and (3) the speed of light, c , which figures prominently in both relativistic and quantum physics. From these three constants, the German physicist Max Planck, one of the founders of quantum theory, found that there was a unique way of using them to define a quantity with the dimensions of length:

$$l_P = (hG/2\pi c^3)^{1/2} \approx 1.6 \times 10^{-35} \text{ m}$$

This quantity is named the *Planck length*. It is very small – about 10^{-20} times the size of the proton. It is often regarded as in some sense

the “natural” unit of distance. What one can say is that any attempt to unite quantum theory with relativity must involve these three constants, and hence any expressions of a distance arising out of the combined theory will involve this unit of length, possibly multiplied by some unimportant numerical factor such as 2π . According to some theories of quantum gravity, this is expected to set the scale where quantum fluctuations become so pronounced that the very structure of space itself breaks up and it becomes a discrete kind of foam – thus setting a limit on the smallest distance that can still have properties recognizable as those of space. But there are other attempts at formulating a theory of quantum gravity that do not point to such a conclusion. The position is unclear, and could remain so.

Space in Relation to Time

According to relativity theory, motion affects spatial distances. For example, a spacecraft flying at high speed is, according to the mission controller, shorter than when it is stationary on the launch pad. Distances are also affected by gravity. Time is also affected by motion and gravity. As explained under the entry *Relativity*, all this points to the idea that space and time are intimately connected as a four-dimensional continuum called spacetime, rather than there being a three-dimensional space and a separate one-dimensional time.

Space and Religion

We have seen how physicists have thrown into question the idea that empty space is just another name for nothing. We have seen that one might just as well regard space as full everywhere with dark energy, full of particles popping into and out of existence, and furthermore as a uniform continuum of negative energy fundamental particles.

Those familiar with attempts of Buddhists to explain Nirvana might see the same dichotomy arising in that context. That blissful state is sometimes described in terms of nonbeing or

nothingness. And yet there is a certain ambiguity between nothingness and plenitude.

Christians contemplating Heaven traditionally thought of it as being “up there” – for example, Christ ascending to heaven. Then it became more a case of “out there.” Neither is satisfactory. With the possibility that there might be further spatial dimensions we do not perceive – either because they are curled up as suggested by string theory, or because they are nothing to do with our spacetime, some might seek to locate Heaven in some of these extra dimensions. But such attempts, in all likelihood, are spurious. Heaven, however it is conceived, is simply not to be described in terms of a physical spatial location.

Space and Time

Arthur Cunningham
St. Olaf College, Northfield, MN, USA

Modern ideas about the nature of space and time have been decisively shaped by the development of physical theory. A few key aspects of the evolution of these ideas can be traced by comparing the conceptions of space and time of Aristotle and Newton, with the conception of spacetime due to modern relativistic physics.

Aristotelian Views

Aristotle identified space and time as features of perceptible entities and processes. His cosmology

described a finite, bounded universe, spherical in shape, with nothing outside of it – not even empty space. Thus, Aristotle rejected the conception of space as an infinite expanse within which material objects are located. He held that regions within the cosmos are necessarily filled with matter and these “places” are properly characterized in terms of the matter by which they are bounded. A region of space, considered as a bare volume, he held to be a mere mathematical abstraction. As for time, Aristotle declared time to be an aspect of change. The time of a change is the quantity of this change, as measured by comparison with a periodic process used as a standard (e.g., the motion of the sun across the sky). In general, then, Aristotle held time to be change considered as quantifiable by comparison with co-occurring changes. Aristotle’s views of time and space were highly influential throughout the middle ages and into the seventeenth century.

Newtonian Absolute Space and Time

The conceptions of space and time formulated by Isaac Newton as part of his system of mathematical physics (first published in 1687) are starkly opposed to Aristotelian views. Newton held the passage of time to be independent of any physical processes, a precondition of change rather than a feature of it. He acknowledged the necessity of using some “sensible and external measure” of time – an observable, regular process – to detect and measure its passage, but he insisted that the “relative” times thus picked out should not be mistaken for “absolute” time itself. Any physical standard for measuring time might fail to pick out intervals of perfectly uniform duration; but “absolute, true, and mathematical time, in itself and of its own nature, without reference to anything external, flows uniformly” (Newton 1726/1991, in the Scholium to the Definitions, p. 408).

According to the *absolute* conception of space championed by Newton, space exists in its own right, as an infinite arena with a Euclidean geometric structure within which material objects can exist. There are locations in space, and spatial relations (e.g., distances) between them, quite

independent of whether any matter exists. Material objects inherit spatial properties and relations from the regions of space that they occupy. Space itself is an enduring entity – one and the same space exists through all times – and each part of space is immovable and unchanging. It follows that a material object has a definite state of motion with respect to absolute space: either its location in absolute space changes over time (absolute motion) or it does not (absolute rest).

Newton posited absolute space in order to provide a theoretical basis for the distinction, central to his laws of motion, between *inertial* (non-accelerated) motion and accelerated motion. Newton insisted that the physical effects displayed by accelerated matter, such as the concavity of the surface of a liquid made to rotate by stirring, could not be understood merely as the results of acceleration relative to other material bodies, and he took such effects as marks of acceleration with respect to absolute space itself.

Gottfried Leibniz, Newton’s contemporary and critic, objected forcefully to Newton’s conception of absolute space. To posit absolute space, Leibniz insisted, is to assign artificial significance to concepts, namely position and velocity with respect to absolute space, that are manifestly nonphysical since they have no discernible effects on matter. Leibniz advocated instead a *relational* conception of space, according to which spatial relations are properly understood as relations between material objects rather than between locations in an independently existing space. Space itself he held to be a purely conceptual entity consisting of all (actual and possible) spatial relations among material objects. In a similar way, Leibniz insisted that time itself was a conceptual entity, arrived at by abstraction from the real temporal relations among objects and events.

Since Leibniz and other relationist critics of Newton were unable to provide an alternative version of Newtonian mechanics, freed from dependence on the notions of absolute acceleration and hence of absolute space and time, Newton’s views came to be widely accepted as the basis of physical theory for the next two centuries.

Spacetime

Albert Einstein's 1905 theory of special relativity resulted in a decisive transformation in scientific conceptions of space and time. Einstein's central insight was that previous conceptions of space and time presupposed a relation of absolute simultaneity that could not be empirically substantiated. He argued that a physical method of determining whether two events are simultaneous, would in fact lead different inertial observers (i.e., observers moving at different constant velocities) to disagree about simultaneity: two events simultaneous from one observer's perspective would fail to be simultaneous as seen by another. Taking this *relativity of simultaneity* to be a fundamental feature of the nature of space and time has profound consequences; in particular, it implies that spatial distances (e.g., the length of a rod) and temporal intervals (e.g., the time elapsed between ticks of a clock) can be assigned a definite magnitude only relative to the state of motion of an observer. These consequences are undetectable at ordinary speeds, but they become significant when the relative speeds involved are a sizeable fraction of the speed of light (approximately 300,000 km/s), which represents an upper bound on the speed with which physical effects can be transmitted; these relativistic effects have been thoroughly confirmed by experiment.

In 1908 the mathematician Hermann Minkowski reformulated special relativity in geometric terms. In this setting, space and time appear as inseparable aspects of a single four-dimensional manifold, *spacetime*. The relativity of simultaneity appears as the freedom to "slice up" spacetime into instants of time encompassing all of space in many different ways. Different slicings give different ways of decomposing four-dimensional spacetime intervals into distinctly spatial and temporal components. The physical equivalence of these many possible decompositions reflects the fact that they amount to descriptions from different perspectives of a single four-dimensional reality.

Like Newtonian absolute space, the spacetime of special relativity has a perfectly uniform

geometry that is unaffected by the matter within it. Einstein's 1915 theory of general relativity, which he devised in order to account for gravitation in terms of the structure of spacetime, gives up both of these features. In general relativity, the geometry of spacetime is determined (in part) by the distribution of matter and energy. Spacetime is curved in the vicinity of a massive body, and it is this matter-induced curvature of spacetime, rather than the gravitational force posited by Newton, that is observed as gravitational attraction. A freely falling (or orbiting) body in a gravitational field is not accelerating under the influence of a force but is following an inertial path (a *geodesic*, the analogue in relativistic spacetime of a Euclidian straight line) in a curved region of spacetime.

Absolute space and time as traditionally conceived have an intrinsic structure that is completely independent of physical objects or processes in space and time. Since in general relativity the structure of spacetime varies with the distribution of matter and energy, the spacetime of general relativity is not absolute in this sense. However, in many models, the structure of spacetime is not completely determined by the distribution of matter and energy; some residual structure is due to spacetime itself, and so general relativity does not support a full-fledged relationism, either. For similar reasons, other aspects of the traditional absolute-versus-relational debate are difficult to settle with regard to general relativity. Multiple distinct issues are bound up together in the traditional debate; these must be pulled apart and considered separately, in the context of general relativity (Earman 1989; Huggett and Hoefer 2006).

Future Physics

Quantum mechanics, our best physical theory of the very small, has yet to be reconciled with general relativity, our best physical theory of the large-scale structure of the universe. Quantum field theory, which unites quantum mechanics with special relativity and spacetime curvature by setting quantum fields within a relativistic spacetime background, has been remarkably

successful. But this approach still represents spacetime as a fixed background structure; a full unification would treat spacetime itself as a fully fledged dynamical entity, subject to quantum-mechanical description (see Rovelli 2001).

The looked-for theory uniting quantum mechanics with general relativity is called “quantum gravity.” There are at present no fully worked-out theories of quantum gravity, only various research programs. Some physicists expect that spacetime will not appear as a fundamental element of a theory of quantum gravity at all but only as apparent or emergent structure within a physical reality whose basic elements are non-spatiotemporal in nature.

For Further Reading

Geroch (1978) is a classic, non-technical introduction to spacetime and relativity theory. Disalle (2006) explains how philosophical reflection by Newton, Einstein, and others regarding presuppositions about space and time played a crucial role in developments in physics. Dainton (2001) is an excellent and accessible guide to a wide range of philosophical debates about the nature of space and time beyond those discussed here.

Spandrel

Matt Rosano

Psychology Department, Southeastern Louisiana University, Hammond, LA, USA

An emergent trait irrelevant to fitness which is later co-opted for some adaptive purpose. Harvard biologist Stephan Jay Gould coined this term making reference to the architectural design of the San Marcos Cathedral. Where the pillars of the cathedral met the vaulted ceiling an open space was created (spandrel). This space was filled with attractive artistic designs. Aside from their artistic contribution, these “fill-ins” did nothing for the actual design of the building. However, this creative use of otherwise useless space stood as a metaphor for how evolution takes left-over or extraneous structures and finds functional uses for them.

Speech

Kenneth Hugdahl
Department of Biological and Medical
Psychology, University of Bergen, Bergen,
Norway

Related Terms

[Communication](#); [Production of sounds](#); [Spoken language](#)

Description

Speech is defined as the acoustic, linguistic, and cognitive processes that lead to the production and perception of sounds used in spoken language. Speech is the vehicle that humans use for symbolic communication. No other species possesses the ability to use speech sounds to communicate. Speech is studied by several academic disciplines including linguistics, phonetics, psychology, speech therapy, neuroscience, and computer science. When speech disorders also are included in the definition of speech, psychiatry, neurology and neurosurgery are three other disciplines that utilize knowledge about speech processes. See Lieberman (1996) and Stevens (2000) for further information.

Self-identification

Science

Speech is self-identified as the topic of study for phonetics and phonology. In other words, the fundamental units of speech; phonemes, morphemes and syllables, and their analysis in a speech context make up the characteristics of speech research. Recent developments in functional neuroimaging, with, for example, fMRI, have moreover established a new discipline in neurolinguistics, where localization in the brain of speech production and speech perception is the major focus. The localization in the brain of speech production and speech perception processes has a long history in linguistics, neuropsychology, speech therapy, neurology, and neurosciences, only reinforced by the more recent introduction of neuroimaging techniques. In the nineteenth century, Paul Broca and Carl Wernicke suggested that areas in the left frontal and temporal cortex were the sites of speech production and perception, respectively. Broca's and Wernicke's discoveries came from close analysis of patients with circumscribed brain lesions to the left hemisphere, which also laid the foundation for studies of hemispheric asymmetry and lateralization. The failure to either produce or understand speech after frontal or temporal brain lesion is called motor or sensory aphasia, respectively, and is typically seen after stroke affecting the left hemisphere.

Characteristics

Speech is a distinctive subtopic in studies of language with its focus on the acoustic properties of language production and perception, including an understanding of the anatomical structures that are necessary for producing speech sounds, that is, cortex, vocal chords, vocal tract, and tongue and lip movements. Speech is however also an integrated aspect of linguistics and in some instances not regarded as a discipline of its own but a subdiscipline of language studies. In recent years, studies of speech processes have also been an integrated and distinctive aspect of

neuropsychology and cognitive neuroscience, with important new theories and models for the understanding of how the brain integrates the acoustic input to words and sentences and produces utterances (Hickok and Poeppel 2007; Tervaniemi and Hugdahl 2003; Binder and Price 2001).

Relevance to Science and Religion

Speech and language is the fundamental vehicle through which humans communicate and is as such critical for bridging humanities and natural sciences, also including the study of religion.

Sources of Authority

The study of speech processes, including the acoustic, phonetic, and semantic aspects, has a long history in the disciplines linguistics and phonetics, and more recent in psycholinguistics, neurolinguistics, and cognitive neuroscience. An influential school of study is the Haskins Laboratory, New Haven, USA, where researchers suggested the motor theory of speech perception (Liberman and Mattingly 1985) and that fundamental speech units, like consonant-vowel syllables are differentially identified by the left and right cerebral hemispheres (Shankweiler and Studdert-Kennedy 1967).

Ethical Principles

Studies of speech production and speech perception follow the ethical guidelines put down in the Declaration of Helsinki for research on humans, and most countries have, in addition, their own ethical committees that evaluate and approve research projects before they are conducted.

Key Values

A fundamental key value is to *understand the basic units of speech production and perception* and how they combine to give rise to meaningful

words and sentences that are understood by other humans, and how this is organized in the brain. A second value is to diagnose and alleviate sufferings from brain lesions and disorders that affect speech production and/or perception, for example, stroke, schizophrenia, dyslexia, and specific language impairment. A special variant of a speech disorder is auditory hallucinations in schizophrenia, where the patient is absolutely convinced that he/she is “hearing voices,” although there is no external acoustic input to the brain.

Conceptualization

Nature/World

Nature is conceptualized from a natural science perspective, that is, as an objective reality independent of the processes that are studied.

Human Being

Humans are considered as biological beings and speech occurs as electrochemical signals or impulses that activate single and/or populations of neurons in the brain.

Life and Death

Life is considered from a biological perspective, and speech is the result of the action and functioning of different organs and structures in the body and the brain, which follows the physical laws of how acoustic waves occur and are transmitted through different media.

Reality

Reality is the physical world in an objective manner.

Knowledge

There exists an objective dimension to knowledge, in the sense of objective truth on a probabilistic nature. That is, phenomena in nature are possible to gain knowledge about only in a probabilistic way.

Perception

Perception is the decoding of the phonological structure of an acoustic signal that gives rise to

a conscious sensation of understanding a message sent by another individual.

Time

Speech occurs in a feedforward time perspective, although speech-related flashbacks can occur.

Consciousness

Speech is a conscious process directed toward another individual, either as intended speech output or as the intended recipient of speech input.

Rationality/Reason

Rationality is/reason is the basis of conscious speech processing.

Mystery

Speech is typically a rational human act but can take on mystery as, for example, in auditory hallucinations in nonpsychotic individuals, who frequently experience “hearing voices.”

Spirituality, African

Augustine Nwoye

School of Applied Human Sciences, University of KwaZulu-Natal, Pietermaritzburg, South Africa

One unique aspect of African psychotherapy particularly in its indigenous paradigm is the use that

is made of the technique of spiritualization and invocation in the social stage of its interviewing process. This is a direct carry over from the traditional African healing systems (Nwoye 2010). It involves the exercise of beginning every psychotherapy process with a prayer intended to make the client believe that he or she is connected to and in the presence of that power from which all good things come and that the healing process to be entered into is approved by God and the ancestors. To achieve this effect the counselor engages in spontaneous prayer and commits his or her effort to the guidance, support, and benediction of these agencies. One who resorts to this technique recognizes and respects the religious view of the client. In this way, the client is made to believe that there are more powers involved in intervening on his or her case than that of the psychotherapist working alone. The African psychotherapist in this way presents himself or herself as a channel of God's intervention in the client's life, with God being presented as the person in the chair of the intervention process. The expected impact of this enlargement in perspective of healing is the spiritualization of the therapy process and ambience. With the atmosphere of therapy spiritualized in this way, the client starts to see himself/herself as within the liminal space rather than in the ordinary counseling office. In this way, again he or she becomes spiritually persuaded to tell his or her story, as it is, without distortion, believing that there are, apart from the counselor, some unseen listeners to his or her story within the counseling room. Through this, an honest narration of his or her story becomes facilitated.

Spirituality and Christian Theology

Andrea Hollingsworth

Department of Religion and Philosophy, Berry College, Mount Berry, GA, USA

Description

In the twenty-first century, the term “spirituality” is utilized broadly and often in opposition to “religion.” However, this current usage has a surprisingly brief history; for centuries, “spirit” and “spirituality” have been closely affiliated with Jewish and Christian religious thought and practice. This entry sketches the etymology, history, and contemporary features of spirituality from the viewpoint of its relationship to Christian theology.

Etymology

Although etymology can only take one so far in understanding the content of Christian “spirituality,” it is a helpful place to begin. Spirituality derives from the Latin terms *spiritus* and *spiritualitas*, which biblical translators used to render the Greek New Testament terms *pneuma* (πνεῦμα) and *pneumatikos* (πνευματικός), respectively. These New Testament terms, in turn, are closely related to the more ancient Hebrew scriptural term, *ruach* (רוח).

Meaning spirit, wind, or breath, *ruach* is connected with *life* in the Hebrew Bible. It is often used in close conjunction with symbols that point toward YHWH's creativity or renewal such as fire, fluidity, and fertility. The authors of the New Testament carried the Hebrew notion of *ruach* into their writings but reinterpreted it in light of their experience of the Spirit as the gift of the risen Jesus to the community of disciples. They called upon the Greek word *pneuma* (“breath of life”) to describe the Holy Spirit of God animating and empowering the community and *pneumatikos* to describe anything under the influence of (or a manifestation of) that Spirit.

Translated into Latin, then, *pneuma* and *pneumatikos* became *spiritus* and *spiritualitas*, from whence we derive spirit and spirituality.

History

The first-century writings of Paul the Apostle suggest that the earliest Christians understood spirituality to mean human life conformed to Christ (Rom. 8:29) and empowered by the Holy Spirit (Rom. 15:13). By participating in the “body of Christ” (or the community of Christian disciples); cultivating the virtues of faith, hope, and love (1 Cor. 13); and appropriating the charisms given to the church by the Holy Spirit (1 Cor. 12, 14; Rom. 12), Christians experienced themselves as being united to Christ and enlivened by the Spirit.

Life “in Christ” and “in the Spirit” was shaped, among other things, by the Greco-Roman culture in which the Christian faith was birthed. In early Christianity (especially monastic movements), contemplative practices from Greek philosophical traditions such as Stoicism and Platonism significantly influenced Christian thought and practice. Early Christian *askesis* (the practice of spiritual exercises) included the deliberate cultivation of such Stoico-Platonic-inspired philosophical therapeutics as attention (*prosoche*), self-mastery (*enkrateia*), and meditation (*melete*) (Hadot 1995). The influence of Greek philosophical categories and practices is notable, for instance, in the theology of Origen of Alexandria (c. 185–253). In his *Commentary on the Song of Songs*, Origen uses Middle-Platonic language to describe the ascent of the soul, which takes place in a threefold manner: *ethike* (amending behavior; keeping commandments), *physike* (recognizing the world’s transitoriness), and *enoptike* (contemplating God in unitive love). For Origen, this threefold contemplative way is the means by which we come to know God, share in God’s divinity (*theopoiesis*), and be thus transformed (Louth 1981).

While we could point to other examples, Origen alone is evidence that early Christianity itself was viewed as a kind of *philosophia* – a

transforming way of life carried out in the power of the divine *pneuma* and in conformity to the divine ► *Logos*. While some chose to carry out this life with special intentionality (i.e., monastics), deification via incorporation into Christ and empowerment by the Spirit was available to all baptized believers. Deification means the process by which humans, already made in the divine image and likeness (Gen. 1:26), are called to become partakers in the divine nature through grace (1 Pet. 1:3–4).

In the Middle Ages, Christian contemplatives writing on spirituality often drew on Platonic and Neoplatonic strains in earlier Christian theologies (e.g., Origen, Augustine, Pseudo-Dionysius the Areopagite), articulating the soul’s inner transformations through symbols of luminosity and ascent. An outgrowth of the *ethike-physike-enoptike* tradition, the so-called threefold way of purgation (purification from sin and its effects), illumination (growth in wisdom and virtue), and union (oneness with God, perfect love) emerged as an important pattern in some strands of medieval Christian thought and practice.

However, spirituality in the Middle Ages was not bound to the contemplative life; *askesis* leading to deification was available to all Christians who pursued the Christ life by partaking in the church’s sacraments and appropriating the Spirit’s *charisms*. As historians of Christian spirituality have shown, through diverse spiritual practices and/or rituals of devotion, and with different theological and scriptural emphases, many medieval Christians (monastic and lay) sought advancement in the spiritual life thereby to attain a more perfect ordering of their soul and a more perfect love of God and neighbor (McGinn 1998).

In the late medieval period and on into the Reformation and post-Reformation eras, *spiritualitas* became exclusively linked with inward, rarefied experiences of the individual soul’s purification, ordering, and exaltation. The concurrent rise of medieval scholasticism with its heavy use of Aristotelian scientific categories contributed to theology’s increased focus on technicality and abstraction. By the sixteenth century, these factors (among others) had resulted

in what some have called a “divorce” between spirituality and theology (Vandenbroucke 1950; McIntosh 1998).

Following this break, the seventeenth- and eighteenth-century Age of Reason strained the relationship between rationality and religion. Moreover, the philosophical “turn to the subject” with its emphasis on individual conscious experience engendered a demand for renewed attention to the subjective experience of religiosity. Thus, post-Enlightenment theologians and philosophers were faced with the problem of finding terminology to describe personal faith in the midst of the double estrangements between spirituality and theology on the one hand and religion and rationality on the other. Able theological minds rose to the task; however, we may point to Søren Kierkegaard, who spoke of “faith” as the absence of despair in which “the self relates itself to itself, and in willing to be itself, rests transparently in the power that established it”; to Friedrich Schleiermacher, who referred to “religious experience” as the “feeling of absolute dependence”; or to Paul Tillich who defined “faith” as “ultimate concern.”

Current Trends

In our late modern situation, disillusionment with institutional religion in the twentieth-century West has, for many, rendered ‘religion,’ ‘religiousness,’ and even ‘faith’ nonviable linguistic options for describing an individual’s experience of self-transcendence and/or transformation. Thus, “spirituality” has become in parts of the academy and the general public a decontextualized placeholder for a large and complex constellation of themes relating to human life, including the search for transcendence, identity, meaning, authenticity, virtue, ultimacy, fulfillment, inner potential, interconnectedness, and morality.

In the last 30 years, spirituality has become an increasingly important topic among Christian theologians. Trends in late modern Christian theology seem to suggest that the breach between spirituality and theology is lessening. Contemporary theologians across biblical, ethical,

systematic, historical, and practical subdisciplines have focused increasingly on spirituality and have treated it in diverse ways according to their particular traditions and scholarly emphases.

However, there is disagreement among recent theologians regarding which overall conception of spirituality ought to be (re)embraced. Some prefer to remain focused on the spirituality of patristic and monastic Christian figures, with concurrent treatments of related doctrinal topics. For example, Hans Urs von Balthasar’s definition of spirituality hews closely to his espousal of a nuptial-Marian ecclesiology; for von Balthasar, spirituality is “the subjective aspect of dogmatic theology, the word of God as received by the bride and developing within her” (Balthasar 1989). Similarly, for Edith M. Humphrey, spirituality is closely tied to pneumatology: “Christian spirituality is the study and experience of what happens when the Holy Spirit meets the human spirit” (Humphrey 2006). These and like-minded theologians would generally be suspicious of notions of spirituality that fall outside the bounds of orthodox Christian teachings.

Other theologians advocate a more broadly circumscribed, less confessional notion of spirituality that is attuned to its meaning and usage in contemporary life. Thus, for Sandra M. Schneiders, spirituality is “the experience of consciously striving to integrate one’s life in terms not of isolation and self-absorption but of self-transcendence toward the ultimate value one perceives” (Schneiders 1990). The upshot of this approach is that it can perhaps more easily accommodate interdisciplinary and/or interreligious exploration and collaboration. Still, others seem to work within a framework that adopts and adapts both specialist (confessional) and pluralist (not or partially confessional) conceptions of spirituality. F. LeRon Shults, for example, carries out a constructive analysis of Christian spirituality that is informed by both doctrinal developments in pneumatology as well as scientific and philosophical insights in contemporary thought (Shults and Steven 2006).

The split between theology and spirituality that began in the Middle Ages and widened during modernity is starting to be healed. But

contemporary Christian theological pluralism and specialization, combined with spirituality's broad and shifting meanings, mean proposed models for reuniting the two are usually complicated and controversial. Most theologians agree, however, that any responsible treatment of spirituality in contemporary theology must be informed by careful historical analyses of Christian spirituality and oriented toward the integration of rigorous conceptual analysis with existentially meaningful experience and practice.

Surgeries in which the corpus callosum (a thick bundle of nerves connecting the two hemispheres of the brain) has been severed, thereby cutting off communication between the right and left hemispheres, have revealed a wealth of knowledge about the functioning of the brain and the specializations of each hemisphere. In part because of split-brain research, we now know that, in general, the left hemisphere is specialized for language and the right hemisphere is specialized for more nonverbal abilities.

Sport, Sociology of

Joseph Maguire

School of Sport, Exercise & Health Sciences, Loughborough University, Loughborough, UK

Introduction

Sociologists of sport critically examine the role, function, and meaning of sport in the lives of people and the societies they form and attempt to describe and explain the emergence and diffusion of sport over time and across different societies. In doing so, they identify the processes of socialization into, through, and out of modern sport and investigate the values and norms of dominant, emergent, and residual cultures and

subcultures in sport. On this basis, they explore how the exercise of power and the stratified nature of societies place limits, and create possibilities, for people's involvement and success in sport as performers, officials, spectators, workers, or consumers.

The sociology of sport, while grounded in sociology, also encompasses research in history, political science, social geography, anthropology, social psychology, and economics. Also, the new offshoots of sociology, such as, cultural studies, postmodernism, media studies, and gender studies, are also used. Sociology of sport is both a theoretically driven and an empirically grounded subdiscipline of sociology. It overlaps with, and is informed by, works on the body, culture, and society more broadly and, contributes to the formation of policy that seeks to ensure that global sport processes are less wasteful of lives and resources. Sociologists of sport seek to generate knowledge that will critically examine the costs, benefits, limits, and possibilities of modern sport for all those involved, rather than focus solely on the performance efficiency of elite athletes, and, in studying sport in the same way they examine religion, law, or medicine, they seek to highlight aspects of the general human and societal condition.

Sociological research also seeks to "debunk" popular myths about sport, critically appraise the actions of the more powerful groups involved in sport, and inform social policy toward sport. Sociologists of sport seek to intervene in sport worlds in several ways. They offer expert advice to government agencies, public enquiries, and commission reports on areas such as drugs, violence, and health education. In addition, they act as advocates for athletes' rights and responsibilities. Researchers have sought to provide knowledge for groups who seek to challenge inequalities of gender, class, ethnicity, age, and disability, particularly with respect to access, resources, and status (Collins and Kay 2003). Sociologists of sport have also argued for the better use of human and environmental resources to ensure that there is a sporting future for generations to come. These, then, are some of the aims and tasks that sociologists of sport have set themselves.

Given that sport brings people together, yet also divides them along the societal and cross-cultural lines that already exist, sociologists probe the coexistence of cooperation and confrontation, power and control. The struggles that shape sport provide rich case studies that highlight broader social questions. For example, consider the question "What is sport?" For sociologists, such a question requires understanding the set of social practices adhered to by a set of conventions. That is to say, an understanding of what sport "is" requires an analysis of the society that produces sport. Sport, then, is a form of collective action, involving a host of different people, connected in particular figurations, and creating particular forms of sport products and performances. Attention has been paid to the "conventional understandings" that mark sport subcultures and govern sport practices and which gives sport a relative autonomy, while also critically examining the extent to which sport worlds are "free" from the political and economic context in which they are situated. The intimate and extensive relations between sport and other social worlds must be traced. For example, sport worlds are interconnected with questions of foreign policy, big business, environmental degradation, the medicalization of social life, and the socialization of citizens of different societies (Coakley 2004).

Sport is then both a separate world and a suspension of everyday life, yet it is also highly symbolic of the society in which it exists and is embedded in wider political-economic and socio-cultural currents. In the context of sport people both experience a form of exciting significance that is rarely, if ever, encountered in their daily lives, and also conduct a symbolic dialogue with fellow participants and spectators that reveals things about ourselves and others (Maguire 2012). Sport, then, can be viewed as a modern morality play that reveals fundamental truths about us as individuals, our societies, and our relations with others. Sport, moves people emotionally and matters to us socially. Sports are mimetic activities that provide a "make-believe" separate setting that allows emotions to flow more easily. This excitement is elicited by the

creation of tensions that can involve imaginary or controlled “real” danger, mimetic fear and/or pleasure, sadness and/or joy. This controlled decontrolling of excitement allows for different moods to be evoked in this make-believe setting that are the siblings of those aroused in real-life situations (Elias and Dunning 1986).

Tie-breaks in tennis, penalty shoot-outs in football, and sudden death play-offs in golf evoke a range of emotions, so much so that by the end of the contest we are emotionally drained. And, unlike a well-performed play or well-acted film, we know that what we were witnessing in sport is real and that the outcome was not determined beforehand. Only when sports are associated with matters of deep cultural and personal significance do they become important to fans. Major sporting events are thus mythic spectacles where fans are provided the opportunity for collective participation and identification that serves as a means of celebrating and reinforcing shared cultural meanings. It is precisely because sports are a separate world that suspends the everyday world that they are able to celebrate shared cultural meanings that are expressed through and embodied by sports men and women. The anthem, the emblem, and the flag associated with sporting contests highlight how teams and individuals represent the nation. If social life can be conceived of as a game through which identities are established, tested, and developed, then sports can be viewed as idealized forms of social life. Its rules and codes of play (such as in golf etiquette) allow for a fair contest and a true test of ability. The “true” champion, playing an authentic match, with integrity, is the “best” expression of this. In this context, it is possible to establish an identity with greater consensual and authentic certainty than in social life itself. We insist on the authenticity and integrity of the contest – on the strict formal rules and their fair enforcement – because we want any differences of worth between us to be based on merit. In real life, our class, race, gender, or religion interfere and rig the game of social life and its outcomes. As such, its victors and losers are profane deceptive illusions. But, on the field of play, it is claimed, sport outcomes are sacred, they are real and

authentic. That is also why champions seek to beat fellow champions: That is the true test. Honor and respect are not achieved by knowing in advance that you will beat inferior opponents (Hughson 2009).

Sport is thus a symbolic dialogue: It symbolizes the strict requirements of how a dialogue should be conducted (Ashworth 1971). Sport, then, involves a dramatic representation of who we are and who we would like to be. The stadia is a theater in which we experience a range of pleasurable emotions and exciting significance: the excitement of the played-game, uncertain as to its outcome but its significance lying in what we have invested in it emotionally, morally, and socially. Sportsmen and -women act as our heroes, expressing both the myths, and revered social values of a society, and the sports ethic that underpins involvement in sport. They have to take risks, to exhibit the hallmarks of bravery and courage and show integrity. Yet, there are, as the sociological account of sport reveals, other sides to the sports experience (Jarvie 2006).

Developments in the Sociology of Sport

Although the first texts on sociology of sport appeared in the 1920s, this subdiscipline did not develop until the early/mid-1960s in Europe and North America (Caillois 1961; Loy and Kenyon 1981; Loy et al. 1981; Stone 1971; Yiannakis and Melnick 2001). A small number of scholars from both physical education and sociology formed the International Committee for the Sociology of Sport (ICSS) in 1965. The sociology of sport is internationally represented by the International Sociology of Sport Association (ISSA, formerly ICSS), which also publishes the *International Review for the Sociology of Sport*. This body is a research committee of the International Sociological Association (ISA) and also an official committee of the International Council for Sports Science and Physical education (ICSSPE). From the mid-1960s, symposia, conferences, and congresses were held annually and theoretical and empirical work was presented. Researchers from different sociological backgrounds began to

develop sociological definitions of sport, conduct pioneering work in different aspects of sport, including sport and socialization; sport and social stratification; sport subcultures; the political economy of sport; sport and deviance; sport and the media; sport, the body, and the emotions; sport violence; sport politics and national identity; and sport and globalization. The subdiscipline has now developed a sophisticated understanding of how people become involved in sport; what barriers they face; and how gender, class, ethnicity, and sexual relations work in sport (Hall et al. 1991). In addition, scholars have developed considerable knowledge about how sport is mediated, contoured by a complex political economy, and bound up in global identity politics (Cornelissen 2011; Lawrence and Rowe 1986).

Main Theoretical Perspectives

As the sociology of sport developed as an academic subdiscipline in the 1960s, it is not surprising that the theories that were used to explain sport were those which were dominant at the time (Jarvie and Maguire 1994; Maguire and Young 2002). In North America, and in particular in the USA, functionalist accounts held sway (Lever 1984). Thus, American-based accounts of sport in the 1960s and the 1970s tended to emphasize that sport reflected society and that society itself was based on a social order where consensus and shared values were evident. Functionalist accounts highlighted that society was made up of a system of interrelated parts that contribute to the satisfaction of system needs and thus to social order. In mainstream functionalist accounts, the “social functions” of religion, education, and law, for example, were assessed in terms of their contribution to meeting the functional prerequisites of society. Sport was viewed in a similar vein. Its social function was and is seen in terms of how, as a social institution, and as a source of personal expression, it contributes to social stability and socialization. Parallels were also drawn between the role of sport and religion. Considered in this way, sport functions

as a “surrogate” religion and acts as a form of social glue that brings and binds people together (Coles 1975; Stevenson and Nixon 1972).

While this approach fell increasingly out of favor in Europe and North America in the 1980s, its influence lingered on in Korean and Japanese accounts of sport into the 1990s. More recently, it is arguable that some of the underlying assumptions of this approach have found expression in the use of the concept of “social capital” to assess the potential of sport to “solve” wider societal and indeed global problems (Putnam 2000).

In contrast to the functionalist accounts provided in North America in the 1960s, European sociology increasingly turned to Marxist accounts to explain the conflicts and inequalities evident within and between societies (Bairner 2007). Drawing on the work of Karl Marx, and others, writers such as Jean-Marie Brohm (1978) and Paul Hoch (1972) focused on the role of economic interests and the exploitative relations built into the capitalist system. In Marxist accounts, attention was given to how economic resources were unequally distributed to the role that social class plays within societies and to how power was based on the ownership and control of the economic means of production. In this light, participation in and consumption of sport was seen to reflect and reinforce class relations. The power elite in the wider society had/have their equivalents in sport: The system of sport is used to maintain the interests of the powerful and its consumption viewed as “distracting” the working class from engaging in a more critical stance against the inequalities of the capitalist system. Indeed, sport itself was viewed as being distorted by the role of capital and broader political and economic interests. The play element of sport was undermined and sport had become, much like the role of religion more broadly, the “opiate of the masses” (Rigauer 1981).

While reaching quite different conclusions about the function and meaning of sport, functionalist and Marxist accounts tended to downplay the role of the individual in shaping their lives and sporting involvement: By and large, sport reflected society and reinforced the existing status quo. Critique and counter-critique between

these paradigms remain a feature of sociology of sport to the present day (Morgan 1994). Within Marxist accounts, however, academics began to question whether the account offered was too economic and deterministic. Instead, in the research of Richard Gruneau (1983) and, in the later work of John Hargreaves, (1985) for example, attention was increasingly given to the role of culture. Throughout the late 1980's and 1990's, neo-Marxist and cultural studies accounts of sport superseded "classical" or orthodox Marxist accounts. Consideration was increasingly given to the role of sport as part of wider cultural relations. Power was viewed as contested, exploitation was resisted, and alternative subcultural responses provided. Sport was viewed as a site where culture was produced and reproduced but also transformed. Sporting subcultures were investigated to assess the extent to which people were repressed and/or empowered. Particular attention was given to the resistance offered by people at the margins of societies. Arguably, the sentiments of neo-Marxists and cultural studies scholars found expression in the more postmodern studies of sport that came to the fore in the 1990s and throughout the last decade (Andrews 1993, 2000; Markula and Pringle 2006; Rail 1998). Indeed, postmodern studies, examining sport in terms of identity politics, consumption, the body, and globalization, have become very popular, especially in North America, and in some ways have supplanted classical Marxist accounts of how best to understand to role and meaning of sport in and across societies.

These postmodern accounts have also been influenced by feminist perspectives (Flintoff and Scraton 2002). This perspective developed later than either functionalist or Marxist accounts and has, since the 1970s, changed considerably in terms of the societal basis of patriarchy, the role that sport plays in this regard and what solutions are offered to overcome gender exploitation. As with other perspectives, feminism is not one thing. Yet, all approaches within this perspective are agreed on the centrality of gender in understanding society. This approach grew in prominence in Western societies and in the academy in the 1980s onward. Initially, liberal feminists were

concerned with ensuring that women had equal access to and equal treatment within sport. Throughout the 1990s, a feminist approach grew in popularity. Some scholars, such as Jennifer Hargreaves (1994), combined a Marxist and feminist approach and used a class and gender analysis to raise questions about the role that sport played not just in reflecting the inequality of society but, in some instances, also exacerbating these inequalities. In particular, the impact of hegemonic masculinity and the role it plays in the biased nature of sporting ideology and content was focused on. The solution to this was viewed not simply in terms of access, status, or resources but rather in a reconceptualization of the meaning and function of sport (Hall 1996).

This perspective was also accompanied by a radical feminist critique that questioned the very structure and meaning of sport. Arguing that sport was inherently unequal and unhealthy, radical feminists argued for separate development and alternative body cultures. This latter emphasis gelled with postmodern concerns focusing, as noted, with the body, identities, sexualities, and consumption. More recently, therefore, feminist accounts of sport have combined with postmodern approaches that probe these questions of identity (Markula 2005). By and large, however, they have tended to be a much more prominent feature of Western scholars and, as yet, have not taken a significant hold elsewhere.

While these approaches have tended to emphasize, to a greater or lesser degree, how sport reflects and reinforces society, there is also a long-standing approach, again dating from the 1960s, that examines sport in terms of how society is created through the exchange of meanings, identities, and culture in interaction with others. Drawing on the work of George Herbert Mead (1934), Erving Goffman (1959), and others, a symbolic interactionist approach, while less prominent in sociology of sport, has provided a counterpoint to more macro and deterministic explanations of the meaning and function of sport. Focusing on small-scale social settings, this approach examines the meanings, identities, and (sub)cultures created in and through

interaction (Donnelly and Young 1988). Attention is given to how social worlds, including sport, are socially constructed by the expression, interpretation, and exchange of meanings (Klein 1993). This approach has proved particularly valuable in probing the socialization into, through, and out of sport (Curry 1991; Fine 1987). In addition, the symbolic side of sport, how it represents identities at local, national, and global levels, has been fruitfully explored. Perhaps its biggest weakness, however, is its inability to explain how these small-scale, micro settings in which the agency of the individual is emphasized and meanings constructed and exchanged, relate to wider social structures and issues of power and inequality.

Two other perspectives that directly address this issue of the relationship between individual agency and social structure have also been extensively used in sociology of sport. These approaches derive from the work of European social theorists Norbert Elias and Pierre Bourdieu. Eliasian or figurational/process sociologists highlight the chains of interdependency that people form and live out their lives in. While active in the ongoing development of interdependency, such chains act back on people in enabling and constraining ways. In examining social change, figurationalists probe the power balances within figurations that influence relationships between individuals, social groups, and societies – between the established and the outsiders. Developed by Elias and Eric Dunning (1986) and others, this approach has examined the emergence and global diffusion of modern sport, the expression of violence by participant and spectators in sports, the role that sport plays as a male preserve in affirming masculinity and male power, the connections between sport and the medicalization of the body (Waddington 2000), the significance of global sport on local and national identities, and the meaning and importance of sport in terms of an individuals and groups quest for exciting significance (Maguire 2012).

With a somewhat similar intent as Elias, Bourdieu sought in his general theory to resolve

the tension between the individual and the society. For him, researchers inspired by his framework, the key building blocks for understanding society lay in probing the connections between the accumulation and investment of capital, the formation of a person's habitus and the gaining and maintaining of distinction. Unlike more Marxist accounts, Bourdieu was keen to highlight that the accumulation and investment of capital involved cultural and social elements as well as economic (Bourdieu 1984). That is, while an understanding of the distribution of wealth and income was a necessary part of any analysis, consideration had also to be given to the gaining of cultural capital (formal qualifications and informal high status knowledge) and the presentation of an individual's social capital as expressed in and through their bodies – accent, demeanor, and body language. Together, these forms of social capital construct social fields in which individuals share with others common life chances, experiences, and tastes. The embodied social memories, or habitus, of an individual, reflects and reinforces the ongoing struggle for distinction, power and status within societies. Sport plays a significant role in both the form of a person's habitus and the accumulation of distinction (Bourdieu 1984; Wacquant 1992). For Bourdieu, and others, the social function of sport serves to reflect the different uses and investments of social capital and the differential rewards that flow from such investment. Sport itself is also marked by the struggles to gain and maintain status – different sports and sport settings require and confer differential distinction on its participants and consumers (Kay and Laberge 2002).

There are other approaches that have been used to explain the relationship between sport, culture, and society (Jarvie and Maguire 1994; Maguire 1999; Maguire and Young 2002). The intention here has been to highlight how the sociology of sport both uses and contribute to wider sociological theory. Informed by these theories, sociologists have focused on the following areas:

1. Culture and socialization into, through, and out of sport

2. The relationship between sport and stratification – particularly with reference to social class, gender, and “race”/ethnicity but also disability
3. The body and the emotions – focusing on the able/disabled body, the technologized body, the medicalized body, the consuming body, and bodies and identities politics
4. The role that sport plays in the generation and expression of deviance: violence by participants and spectators; drugs and pain and injury
5. The connections between sport and local, national, and global spaces and places – with particular reference to issues of political economy, migration, national identity, and the media

Why Sport Matters?

Any study of sport which is not a study of the society in which that sport is located is study out of context. In order to make sense of society – and how sport both reflects and reinforces societal structures and subcultures requires theoretical insight and empirical enquiry of the kind outlined above. The facts about sport and society do not speak for themselves: sociological theories both help us make sense of our observations and assist in development of an analysis and explanation for the patterns we observe. The interplay between theory and evidence lies at the heart of the sociological imagination that seeks to make sense of history, biography, and social structures (Sugden and Tomlinson 2002). Hence, the study of sport sheds light on both the subcultures of different sports but also the society in which such sports are located. Through the seemingly mundane and unserious aspects of sport, the sociologist can see the serious and significant aspects of society and the human condition. This can be illustrated with reference to the role and significance of champions in sport. That is, what is it to be a sporting champion and why do they mean so much to people in different cultures and civilizations – be in Western or non-Western cultures? In a simple sense, a champion is someone who is

the first among all contestants or competitors, and in this regard, the word refers to the ability of an individual or team to win a contest or championship. Yet, the origin of the word, in English, indicates a different usage and offers a clue as to why champions are so much more important to us than just their ability to win and why people across the globe attach such meaning to them. Its first usage, in English, emerged in the context of the medieval tournament and referred to the person who would act as a champion of others; who would defend, support, or *Champion* a cause (Hughson 2009). Athletes are not simply champions of their sport, but also of their local community and nation and, sometimes, humanity as a whole. An example of this is the American boxer, Muhammad Ali. A champion is said to possess special gifts and exude a certain charisma: They perform “miracles” and achieve the seemingly impossible. Athletes, for better and for worse, are our modern heroes: symbolic representations of our cultural values and who we would wish to be. Champions are talented individuals, but as heroes, they are people whose lives tell stories about ourselves, to ourselves, but also to people from other nations (Huizinga 1947/1955).

People from different cultures appreciate excellence and have a desire to achieve it, and if not, then at least to share in it. The champion allows us to catch a glimpse of what we could be: By representing us, they make us vicariously fulfilled human beings. They are our modern heroes because sport has become the forum in which communal self-revelation occurs. That is, modern sport is a form of surrogate religion and popular theater in which there occurs the communal discovery of who we are. Sports stadia are contemporary venues in which we can observe champions as heroes and experience the “sacred,” moments of exciting significance, while leaving behind the profaneness of ordinary life. In this sense, society needs its champions as heroes. They perform the manifest function of achieving sporting success for themselves and their local community and nation. But they also perform a more latent role: They are meant to

embody the elements that a society values most. As idealized creations, they provide inspiration, motivation, direction, and meaning for people's lives. Champions as heroes act to unify a society, bringing people together with a common sense of purpose and values. That is how modern sport developed (Guttmann 2004). Pioneers of the nineteenth century linked sport to Western muscular Christianity: unselfishness, self-restraint, fairness, gentlemanliness, and moral excellence. This was itself supplementing traditional notions of chivalry: honor, decency, courage, and loyalty. These qualities are some of the very attributes associated with what people describe as the "true" champions.

Despite this sense of nobility, there are, however, threats to the manifest and latent functions of champions as heroes. This stems from issues associated with authenticity and integrity. The status of the champion relies upon the authenticity of the contest. If the contest is tarnished by corruption, cheating, drug taking, or betting scandals, then the hero is diminished in our eyes. The contest is no longer either a mutual quest for excellence or societies forum in which communal self-revelation occurs. This lack of authenticity also occurs when the sport becomes too make-believe, is rigged, or becomes too predictable. Professional wrestling may produce "champions" but they are not taken seriously, and they are not our heroes. In addition, if the champion represents a state system that the people do not support, then their respect is lacking. Alternatively, athletes can become signs of resistance and offer glimpses of different social systems (Dyck 2000).

The champion can, as hero, embody the elements that a society holds most dear. But the integrity of the champion may also be undermined in several ways. The champion may be a flawed genius – either due to the fact that they suffer from hubris and feel they need not dedicate themselves to the level and intensity of preparation and performance required, and/or because their private lives intrude on their status as heroes. Our idealized image of them as athletes is shattered. In addition, our champion maybe less a hero and more a celebrity – they are famous but not heroic. David Beckham may be seen in

this light. If this be the case, such fame is short lived and they fail one of the tests of a true champion as hero – the test of time. Celebrity sport stars can once be famous, but be neither a champion nor a hero, and is now forgotten. In order to understand why champions mean so much to us and what impact they have, we have to consider the role sport plays in society. This is where sociological theory helps and why the insights from this subdiscipline are so crucial to an understanding of sport and society (Coakley 2004; Tomlinson 2005, 2007).

Stereotactic Surgery

Wilhelm E. Eisner

Department of Neurosurgery, Medical University
Innsbruck, Universitäts-Klinik für
Neurochirurgie Innsbruck, Innsbruck, Austria

A special kind of neurosurgery utilizing a frame attached to the skull of the patient. By referring to a Cartesian coordinate system, every point around the frame could be defined by a x, y, z coordinate system. A special targeting arm, attached to the frame, enables to reach every place or point inside the skull with a high precision. It is used for taking biopsies from the brain, for removing tissue like abscess or hematomas, and for placing electrodes or radioactive tissue within the brain.

Stress

Carolyn M. Aldwin and Michael R. Levenson
Program in Human Development & Family
Sciences, Oregon State University, Corvallis,
OR, USA

Stress is a multifaceted construct which can be viewed in three different ways. First, stress refers to a state of the organism in which physiological processes are activated which leads to heightened arousal, including faster heart and respiratory rates, glucose is released into the blood system, and cognitive and skeletomuscular processes are heightened. Second, stress can also refer to environmental challenges which can be physical or psychosocial, such as exposure to environmental toxins, loss, or other threats to well-being. Some researchers distinguish

between strain (state of the organism) and stressors (environmental challenges). Others refer to stress as a transaction between the person and the environment, in which environmental requirements strain or exceed the individuals' resources to cope. In this system, appraisal processes are central, and result from an evaluation process through which the individual decides whether a situation is benign or whether it involves a threat, a harm or loss, or a challenge. Aldwin (2007, p. 24) defined stress as "that quality of experience, produced through a person-environment transaction, that, through either over-arousal or under-arousal, results in psychological or physiological distress."

There are several different ways to assess stress. Trauma refers to situations which are life-threatening or may result in serious bodily harm, either to oneself or others. Life events refer to major changes in living situations, often due to changes in social roles, such as divorce, job loss, or bereavement. Daily stressors refer to more minor problems which occur in everyday life, such as traffic congestion or arguments with friends and family, and are often assessed through daily diaries. Chronic role strain refers to ongoing problems such as poverty, chronic job stress, or caregiving. Finally, microstressors are assessed through ecological momentary assessment, in which individuals are "beeped" and asked to report on what they are experiencing at a particular moment.

String Theory

Russell Stannard
Department of Physics and Astronomy,
Open University, Milton Keynes, UK

This is a theory that the fundamental building blocks out of which matter is made consists not

of point-like particles as previously thought but tiny vibrating strings. It is the different modes of vibration of the string that gives rise to the particle's properties. It is believed that such strings vibrate in up to 10 spatial dimensions. As we experience only three spatial dimensions, it is claimed that the extra dimensions are curled up too small to be detected.

Supervenience

Gregory Peterson
Department of Philosophy and Religion, South
Dakota State University, Brookings, SD, USA

A term used to conceptualize the relationship of mental and physical properties within a physicalist perspective, without necessarily reducing mental properties to physical ones. Typically, a supervenience relation is understood to hold if one set of properties (the mental) are understood to depend on another set of properties (the physical), and any change of property at one level entails a change at the other level. An extensive philosophical literature surrounds supervenience, with considerable debate over whether supervenience relations allow for mental causation and whether they support non-reductionist interpretations of mind-brain relations.

Surgery

F. Catena
General, Emergency and Transplant Surgery

Bologna, Italy

Related Terms

[Medical procedure](#); [Surgical procedure](#)

Description

Today in Europe, surgery is devoted to offering detailed diagnostic criteria and therapeutic

regimens for diseases affecting all the body that need a surgical operation. The term surgery was derived by the Greek word *kheirourgos* that means “man that operates (*ergon*) with his hands (*cheir*).” Throughout Europe, surgery became a discipline of its own right at the end of the nineteenth century, being treated as a separate entity distinctive from *medicine*. This development started in the university hospitals and was followed by the establishment of separate departments of surgery in most major community hospitals and, in the second half of the twentieth century, with the development of specialized subdisciplines such as vascular surgery, cardiac surgery, thoracic surgery, etc.

Self-identification

Science

Surgery has self-identified, from its very beginning, as a medical science. It sees itself as a scientific endeavor with the aim to develop the knowledge about the diseases that can be treated with an operation. The disease concepts and related surgical procedures were developed in the twentieth century with the birth of general anesthesia. The increasing knowledge of the surgical pathology is considered as a fundamental basis for specific surgical procedures. Surgery is one of the so-called natural sciences because it applies the scientific methods of the natural sciences for clinical and basic research as well as for diagnostic procedures and therapeutic procedures. Progress in surgery is characterized by the development of specialities such as cardiac surgery, vascular surgery, thoracic surgery, pediatric etc.

This was pioneered by the turn of the century with the clinical triumphs of various English surgeons (R Tait, W Macewen, F Treves), German surgeons (T Billroth, T Kocher, F Trendelenburg, J von Mikulicz-Radecki), French surgeons (J Pean, J Lucas-Championniere, M Tuffier), Italian surgeons (E Bassini, A Ceci, G Tagliacozzi), and US surgeons (W Williams Keen, JB Murphy).

In the second half of the twentieth century, surgery expanded over *organ transplantation* as

the medical basis of these operations became available (immunosuppression).

A new focus of scientific work in surgery has been to elucidate the *role of minimally invasive surgery*. This involves all surgical disciplines.

More recently, surgery was also equipped also with robotic assistance.

Nevertheless, with the discovering of new medical treatment, some surgical procedures were abandoned (e.g., gastric resections for peptic ulcers).

In more recent times, multicenter randomized double-blinded studies have become very important to establish evidence-based guidelines for surgical treatments.

The increase of knowledge in the different surgical disciplines has fostered the emergence of a broad range of independent surgical specialities. This is reflected by dedicated national and international scientific organizations and separate educational pathways. In addition, many specialized societies have been founded addressing specific diseases/operations or research topics. These organizations arrange their regular scientific meetings and in the majority have their own scientific journals. These societies show increasing numbers of members.

Characteristics

Surgery is distinctive among other specialities of medicine because it is based on the surgical therapy. This particular aspect of surgery guides the surgeon in considering all diseases that cannot be treated only with drugs.

In contrast, diseases in *internal medicine* typically are treated with drugs.

Relevance to Science and Religion

Surgery sees itself as relevant *to, interested in, the scholarly area called Science and Religion because in the field of organ transplantation, many religious issues are discussed, but also in the field of surgical indications in high-risk patients, many religious and ethical issues are present (euthanasia).*

Sources of Authority

The authorities in surgery used to be scientifically interested surgeons who were also fundamental for the establishment of famous academic institutions.

For example, the origins and history of the Royal College of Surgeons of England lie in the union of the Fellowship of Surgeons and the Company of Barbers by Henry VIII in 1540 to form the Company of Barber-Surgeons. They maintained a somewhat uneasy partnership in the sixteenth and seventeenth centuries when the degree of surgical intervention was limited. The eighteenth century, however, saw the rise of private anatomy schools and the development of an academic basis for surgical practice through the teaching and publications of the leading European surgeons. As a consequence, the number and importance of surgeons increased, along with a firm desire for independent professional recognition. In 1913, the American College of Surgeons was founded.

Among the great difficult technical problems faced by the nineteenth-century surgeons was that of reconnecting the divided ends of hollow tubes, especially blood vessels and bowel. The successful appendectomy, the Billroth operations for esophageal and gastric cancer, and the improved hernia repairs of Bassini and Halsted, all caused great excitement in the medical world at the end of the nineteenth century.

Before antisepsis was introduced, laparotomy was not usually possible. The basic principle of bowel suture was discovered in the nineteenth century by Guillaume Dupuytren and John Hunter; Dupuytren's student, Antoine Lembert, is known for his suture.

In America, important contributions to the advance of surgery were from the work of Charles McBurney of New York and John B. Murphy of Chicago. Charles McBurney described the point of maximal tenderness in appendicitis and proposed a new incision for appendectomy.

The successful treatment of an abscess of the appendix in King Edward VII of England helped break down the resistance to surgery.

With the advent of the web, electronic publishing, and electronic libraries, original papers in surgical journals have become widespread.

Surgical scientific societies have established guidelines for *good clinical practice* and evidence-based guidelines which are constantly updated for therapeutic protocols of the major surgical diseases.

Ethical Principles

As for every medical subdiscipline, surgery is guided by the oath and law of the ancient Greek physician *Hippocrates* (born 460 B.C.) who is considered the so-called father of medicine. This "Hippocratic Oath" has been supplemented by the rules of the Declaration of Helsinki of 1971.

Key Values

The key value of surgery is treating human *diseases* with a surgical procedure. A second key value in surgery is that of diagnosing, treating, counseling, and guiding patients before and after the operation.

Conceptualization

Nature/World

Nature is conceptualized as the *biological* and *biochemical* foundation of life on our globe. The world comprises the material and the interspersed space of the universe.

Human Being

The human being is considered as a biological being equipped with unique capacities of the human brain.

Life and Death

Life is conceptualized as the presence of physical functions in biological systems; death is considered the cessation of such physical functions. A special case, which has raised ethical

challenges for transplant surgery, is that of so-called brain death: bodily functions are partially maintained, but there is no evident brain activity. In this case, it is possible to proceed to organ retrieval for transplantation.

Reality

Reality is considered the world around us that human beings can observe with their senses.

Knowledge

Knowledge is the *wisdom* that can be transferred in a verbal form or has been written down.

Truth

Truth is conceptualized as the supreme reality in accordance or agreement with facts and rules.

Perception

Perception is the *conscious sensation* of the external physical world on living human beings. Anesthesia during surgery cancels or impairs perception.

Time

Time is the fundamental category of ongoing change in past, present, and future. Human perception of time can be affected by anesthesia during surgery.

Consciousness

Consciousness is the responsiveness of human beings to any physical stimulus. Anesthesia during surgery can impair consciousness globally, or in differentiated fashions.

Rationality/Reason

Rationality is a foundation of accountable and *responsible* human comportment. It is impaired in anesthesia during surgery.

Mystery

For definition, surgical diseases have a clear cause that can be treated with a surgical procedure.

In surgery, the only place for mystery is what is as yet unknown.

Relevant Themes

A critical issue in surgery as regards “Science and Religion” is the idea of the surgeon’s “hands” guided by God during their difficult work. Many religious patients and surgeons think that this could be possible.

Synapse

Neil Spurway
University of Glasgow, Glasgow, Scotland, UK

The junction between a nerve and the next cell in an information chain – another nerve, or a muscle or gland cell located to carry out neuronal instructions. At almost all human (and other vertebrate) synapses the signal is conveyed by the extremely rapid diffusion of a “transmitter” chemical across a tiny gap between the cells. Two important properties follow. Firstly, because only the “output terminals” of the transmitting cell have the means to make and release transmitter, and only the underlying membranes of the next cell have the means of responding to it, transmission can occur in only one way across the synapse. And secondly, it is at synapses that the great majority of other chemicals, from hormones to drugs, act on the nervous system. The number of synapses is huge: there are about 10^{14} nerve cells in a human body, and large cells may have 10^4 synapses on their surfaces. It is considered that learning, memory, and many neurological aspects of both development and aging are mediated by synaptic changes.

Systematic Theology

Jan-Olav Henriksen
(MF) Norwegian School of Theology, Majorstua,
Oslo, Norway

Overview

Systematic theology (ST) is a scholarly discipline within the context of Christian theology, aiming at relating the contents of faith to the present stand of knowledge. ST presupposes the existence of the Christian religion and relates to this religion in a constructive as well as critical manner. The outcome of the work in ST is a comprehensive articulation of the content of Christian faith within the horizon constituted by contemporary knowledge.

Description

Systematic theology (ST) is the attempt to articulate a coherent and normatively acceptable understanding of the content of ► [Christian faith](#) in the light of the following: (a) the teachings of the ► [Bible](#) and the tradition of the Church and (b) present experience and established knowledge. This task is carried out while reflecting on the conditions for understanding and interpreting the world as well as the teachings of the Bible. Hence, the whole enterprise of systematic theology involves pragmatic, hermeneutical, and contextual considerations.

In a historical perspective, emphasis in systematic theology has shifted from a coherent and encompassing systematization of the usages of the Bible relating to doctrinal topics ((a) above) toward a more philosophically, hermeneutically, and historically reflexive and comprehensive

articulation of the possible content of this faith under present terms of knowledge ((a) and (b) taken together). Moreover, systematic theology has today to be differentiated from ethics and philosophy of religion, which often are seen as the neighbor disciplines of ST within the study of theology. It also cannot be identified with doctrinal theology (a mere exposition of the doctrines of the Church), as it will have to discuss critically the conditions for, and content of, such expositions.

The *pragmatic* scope and context for ST is related to the Christian Church. As a systematic articulation of the content of Christian faith, ST aims at making this faith as transparent and as viable as possible in the light of knowledge from all the sources above, solving the different problems emerging in the present situation from the point of view of Christian faith. The pragmatic dimension implies understanding *how* Christian faith makes a difference in relating to the world, why it makes a difference, and *what kind of difference* faith in the triune God makes.

The *hermeneutical* dimension of ST is constituted by the relation of classical texts of Christianity (the Bible, the ecumenical and confessional creeds) with a normative status to the present-day insights, knowledge, and experience. To interpret the contents of Christian faith within the horizon of the present context is the main task for ST. Hence, ST cannot be understood simply as the summa of what the Church did believe in the past – as such historical reconstructions are never sufficient in order to relate the content of faith to contemporary contexts, with their implicit or explicit conditions for understanding what the faith implies and with what problems the contexts challenge it.

ST is accordingly an attempt to articulate versions of contemporary, viable, and *scholarly and scientifically informed understandings of Christian faith*. These articulations emerge out of different contexts, and are conditioned by the knowledge, the problems, and the traditions of these different contexts, but are nevertheless often done in a manner that also relates to other versions of such articulations, be it from a confessional, socially, or theoretically different

point of view. This engagement across different positions makes it possible to have a *reasonable* and *warranted* assertion of ST that is more than a mere confessional statement of what a given group of people, Church, or theologians hold as their private opinion.

The articulations of ST can be done in a manner that *incorporates* all relevant material and understanding within one (more or less) coherent and explicitly Christian understanding of the world as a given frame of reference (narrative theology, postliberal theology, Barth, Jüngel, Hauerwas) in a manner that tries to explicate the contents of Christian faith over against and in relation to other realms of knowledge (Pannenberg, Tracy, Tillich) and in a manner that is also willing to discuss to what extent there is a possibility for relating the contents of Christian faith to the present amount of knowledge. The latter mode of doing ST is more likely to grant the modern way of looking at the world in a relatively independent normative status, despite the fact that some of the preconditions for a modern understanding of the world is still discussed or put to scrutiny.

Among the more recent developments in ST is the realization that as theology, like any other field of knowledge and scholarly work, is historically and contextually bound in all its different aspects, the modern quest for one coherent and objective articulation of what faith is is left as an unwarranted illusion that neglects the historical and contextual dimension of all forms of knowledge, including theology. Acceptance of plurality and of different theological positions has thus become more apparent and necessary, and it has resulted in discussing the normative status of theology from a lot of different perspectives, where none can claim more privilege than others. As a result, previous types of confessional theology seem, in many places (at least in the academy), to recede to the background.

Another important development in ST is its increasing interaction with other subjects in the university, be it social sciences, natural sciences, or parts of humanities. The interaction with and employment of resources from these areas are today becoming an increasingly more important

horizon for the articulation of theology, be it in everything from understanding the political implications and dimensions of religion over gender studies to the information provided by present results in the natural sciences. In principle, ST should be done within a university or university-like setting in order to fulfill its intellectual responsibilities toward other scholarly and scientific disciplines, as well as its obligations toward the Church for which it is assigned to articulate a viable version of its faith.

Self-Identification

Science

ST self-identifies as a scholarly or scientific enterprise as it relates to and, to a certain extent, has to engage with and interpret the results of science. Without being informed by the results of science, ST would not be able to articulate a viable contemporary articulation of Christian faith. By presenting the articulation in a transparent manner that makes explicit the contextual, hermeneutical, and pragmatic considerations that condition the articulation, as well as what resources and texts it draws on, ST is able to present its conditions and its results as scholarly work that can be discussed, contradicted, or accepted by others. These features condition the scholarly or scientific status of ST.

However, as ST interprets scientific results within the framework of Christian worldview, or as part of what constitutes its contemporary meaning, this does not mean the theology itself is *producing* scientific results in the manner that it makes predictions possible or can explain phenomena in the same manner as does, e.g., natural science. ST provides a possible and as much as possible *understanding* of phenomena within a coherent *interpretative* framework and not a scientific *explanation* of the isolated individual phenomena as such.

Religion

ST self-identifies as part of religion as it is an attempt to make a coherent and transparent articulation of the contents of religion within the

context of contemporary society. It presupposes the existence of religious convictions, faith, praxis, and attitudes as its given basis but reflects on, criticizes, and relates to these givens of religion in all possible ways, both critical and constructive. In this way, it is based on religion, and it can also have impact on present religious view to the extent that what is done as theological work is received and recognized as important in the constitutive pragmatic context of theology, i.e., the Christian Church.

Characteristics

The distinctiveness of ST over against the other historical disciplines of theology is that it is explicitly dealing with how it is possible to articulate a *potentially normative* (i.e., true, coherent, and acceptable) Christian faith in the contemporary world, on the conditions that are given with the present universe of knowledge and understanding. *Historical* theology does not in the same way have the present situation as its constitutive pragmatic context and as their sole hermeneutical horizon.

Relevance to Science and Religion

The understanding of the dimension of human life that expresses itself in religion is something that needs to be addressed, inquired, and interpreted from a multitude of scientific perspectives. It does provide us with a better understanding not only of what it means to be human and of how and why we relate to the world as we do but also of the moral and spiritual dimension of these relations. ST provides articulations that other disciplines can relate to and discuss and may have a clarifying, a critical, and a constructive engagement to offer in relation to the approach to religion that other disciplines have.

ST is interested in the scholarly area science and religion simply because it cannot afford to ignore the scientific horizon as one of the present conditions for interpreting and articulating a contemporary understanding of what Christian

faith is. Moreover, much of what the result of science is both conditions and restricts what kind of articulations of faith theology is able to offer, given that ST works under the requirements set forth by a coherentist understanding of truth. From that position, science is relevant to all areas of faith, including understandings of the origins of the world, of humanity, of morality, of the ecosystem, etc.

As a result, it is hard to see how academic work in ST today can be carried out in ignorance or neglect of the results of other disciplines. Put strongly, it is a requirement for ST as a scholarly enterprise with academic recognition that it relates to and is informed by what takes place in the science and religion debates. Teachings of religion that fails to fulfill such requirements will, at least in a European context, usually not be considered as academically acceptable or satisfactory ways of practicing the discipline.

One of the important consequences of this is that some work in ST is needed in order to overcome the problems emerging from a naïve religious outlook that takes the convictions of a religious tradition to be a competitor to what is the present stand of scientific results. Hence, ST has a mediating role when it comes to relating the content of religious traditions with sciences.

Sources of Authority

The basic source of authority for Christian ST is the ► [Bible](#). As the main source for access to the preaching of Jesus of Nazareth and the Early Church, its status is unchallenged. The main reason for seeing the Bible as authoritative is this content, and it was from early on understood as such by the ► [Church](#) in order to safeguard the main contents of Christian doctrine and preaching. However, in what respect it is authoritative depends largely on what kind of hermeneutical approach one employs when using it. In the modern period, the authoritative status of the Bible does not imply taking anything it says for granted or unquestioned. Many of the conflicts emerging between Christian religion and

modern science do, however, result from a lack of understanding of the historical character of the biblical sources, allowing them to have authority also in matters of science. Recent ST who employs different hermeneutical approaches to the Bible questions and criticizes this use of it and attempts to establish the authoritative elements of Christian teaching (more or less) in consonance with the results of science.

In addition to the Biblical sources, the different ecumenical and confessional creeds of the Christian Churches also play a restricted role as authorities that ST has to relate to. Moreover, in Roman Catholicism, the decisions of the Holy See (the Pope) also have authoritative status.

A generic feature is that the authoritative status of all the above is constantly, in some way, *negotiated* in terms of their relation to the present stand of knowledge.

Ethical Principles

The ethical principles are *fairness* to positions described or discussed, *coherence* with regard to the knowledge established, *reliability*, *transparency*, *openness*, and *corrigibility*.

Key Values

The key value of ST is its result: the presentation of a viable version of Christian faith in the light of contemporary status of knowledge.

Conceptualization

Nature/World

The nature and the world are seen as the result of God's loving creativity.

Human Being

The human being is seen as created in the image of God – i.e., as the being called to represent in a specific way God's love, care, mercy, and compassion for all of creation.

Life and Death

As God is seen as the source of life, all life emerges from God's creative activity. God sustains life through God's own power. Death implies being separated from God's loving power. This separation is usually interpreted as the consequence of sin, meaning that humans reject God and install themselves as God instead. Hence, life and death both have a spiritual and moral, as well as physical, dimension. (cf. below).

Reality

Reality in ST is seen as having a physical, moral, and spiritual dimension. Hence, in ST no priority is given to the physical approach to the world, just as important is the way human relates to reality by moral or spiritual means.

Knowledge

Following the above, knowledge implies more than the mere acquisition of "objective physical facts." It means to take part in and explore the reality of God, in all its different dimensions. Moreover, the knowledge established within a specific scientific discipline is not regarded as sufficient to provide full understanding of reality, as reality basically cannot be fully understood without reference to God.

Truth

In ST, truth must be understood as that which emerges from a coherent interpretation of reality, given the different sources for knowledge and insight. A coherentist approach to questions of truth allows for ST to take fully in the results of different sciences and to be informed by them when it articulates what Christian faith means in the contemporary world.

Perception

Perception is a way of taking part in the world of God.

Time

Time is one of the dimensions in which God allows for the world to exist.

Consciousness

Consciousness is among these capabilities that ST usually describes as soul, although the soul also comprises the subconscious and the emotional dimension.

Rationality/Reason

Reason is the capacity to share in the reality of God and to acquire knowledge of it. However, in ST reason is not reduced to what follows from perception or logical deduction – reason also implies taking into account the moral and spiritual dimension, following the common rules of argumentation, deduction, and inquiry. To be noted is the fact that reason presupposes understanding us as being part of God's creation, not as standing over against it. Hence, reason has its created limits.

Mystery

Mystery is (a) God, (b) the fact that the world is, and (c) anything that goes beyond what human reason has the capacity to explore fully – which from a Christian point of view means literally everything. Hence, in one way, ST is articulating the contents of the mystery of the world by trying to articulate what can and cannot be said.

Literally “affirming the one”: monotheism. Unicity of God, Oneness of God. Monotheism is the cornerstone of Islam. The doctrine of Tawhid signifies total obedience and submission to God in worship and in deed. Tawhid designates the oneness of God (Divine Unicity), his absolute existence, and that he has no equal. It is embodied in the first profession of faith in Islam: “there is no god but Allah’ (la ilaha ilia Allah).”

Technonature and Theology

Anne Kull
University of Tartu, Tartu, Estonia

To access nature, we have recourse to a few analogies: nature as organism, nature as machine, nature as history, nature as cybernetic information-processing entity, and nature as a product of discourse. Not so long ago, scientifically minded humans tended to understand ► [nature](#) as an objective, causally determined realm of matter-energy in motion, void of meanings and inwardness.

New scientific knowledge, from astrophysics to evolution to genetics and molecular science, has occasioned various reconstructions of the idea of nature. Nature has turned out to be not an eternal object but inherently an unstable concept, prone to change dependent on the cultural and historical context. No single image, model, or metaphor does convey the complexity of nature or its meaning for humans.

Neither is there an inclusive image for the human nature and culture, nor ► [technology](#). Technology is usually thought to be about a set of skills, techniques, and activities for the shaping of materials and the production of objects for practical ends. Traditional technologies arouse not from science but from experience and experimenting. Since about the 1850s, technology has been increasingly based on science. And vice versa, instruments and technologies play an ever increasing role in science. Our science is technoscience, and our nature is technonature. The growth of science was paralleled by the emergence of a strong tradition in the philosophy of science and science-and-religion dialogue; the ecological crisis occasioned a variety of philosophies and theologies of nature, whereas the corresponding technological innovations did not generate comparable explosion of philosophies or theologies of technology even though technology figures more prominently and often more problematically in the lives of most people than does pure research science. Since the 1990s, Donna Haraway, Don Ihde, Bruno Latour, Andrew Pickering, Katherine N. Hayles, Sandra Harding, Philip Hefner, and others have been talking about technoscience. The studies in technoscience are deeply interdisciplinary, stretching from philosophies of science and technology to sociology of science to literary and cultural studies to semiotics to theology. All these studies are immensely interested in materiality, all emphasize non-neutrality and ethical-political aspects both in their research areas and their own work. Technoscience and technonature force us to realize that the technology is not so easily distinguished from the “human” since it can be within the body and outside; we can inhabit it (a climate-controlled room) or it can inhabit us (a pacemaker). Discussions of technology are inevitably the reverse side of the coin in debates about human nature.

Theological idea of nature has emphasized that nature is creation. In biblical language, nature (“the heavens and the earth”) is created by God. As a theological construct, nature is a space in which the encounter with God becomes

possible. The full theology of God’s creation involves both the gift character of creation (*creatio ex nihilo*) and the ongoing gracious presence of God in creation (*creatio continua*). The human creature is created of the earth as creatures who alone are created in “the image of God,” the idea of which has several interpretations in the Christian tradition (*imago* as freedom of the will, reason, external or internal likeness to God, capability to have personal relationship with God, of being God’s counterpart, dominion over the earth). Both nature and human nature were basically determined by their beginning.

In 1927, Paul Tillich wrote, concerning the place of mythos of technology in the ultimate meaning of life, “We no longer have a mythos that expresses itself in symbols as past times had. We cannot determine a place for technology as they did. We can only contemplate the matter itself and interpret it and hope that in the interpretation something resonates from the hidden, symbol-less mythos that sustains our time and gives it meaning” (Tillich 1988; Paul 1988, 59). In 1928, he presented his “The Technical City as Symbol” for his age. It can be argued that in the *cyborg* figure, a symbol has been found to interpret our time and our technologies and ourselves.

This Donna Haraway’s most famous “figure” or metaphor or symbol for the role of materiality in human life combines more than humans and machines; it brings together events and dimensions which include technologies, social enactments, and modified biological processes – everything from genes to the socialized military-industrial powers. The cyborg is unfaithful to its origins in the military and Cold War space research context; scientific and medicinal use of the cyborg was rapidly joined by its use as a metaphor of cultural semiotics. Just as the cyborg is about control, and high technology, it is also about the “lived social and bodily relations in which people are not afraid of their joint kinship with animals and machines” (Haraway 1991, 157).

The cyborg destabilizes knowledge to make space for faith that human being is undefinable, fictional, factual, and fantastic – because it is capable of putting one’s own mode of being into

question. The cyborg has many forms, and none of them is “necessary” – it is variously a man in space, or chimpanaut Ham; a socialist feminist; an ecofeminist; a woman of color; a postmodern collective and personal self; a character in a feminist science fiction; a trickster; and a vampire. Technonature consists of innumerable hybrid objects. Transuranic elements and transgenic organisms are at the same time ordinary, natural, and artificial productions of technoscience, invented and copyrighted nature. They challenge the sanctity of life, the well-defined self, and the “purity of kind” thinking. They transform nature into culture. Technonature means that nature cannot symbolize any more immutability, cannot be a symbol for the given parameters of human existence, and cannot found immutability of social relations system – kinship.

If we look for nature outside of ourselves and our practices, we may lose both ourselves and nature. Technonature is a topic which has not been stabilized yet, and thus, we can influence what is going to count as “normal” and “natural”: what forms of life will make up nature for us. Technology can be understood as natural in a double sense – as something rising naturally out of the nature of the humans in the most extensive way, on the one hand, and as a part of “all” that exists, on the other hand. Philip Hefner (Hefner 2003, 34–40) has discussed technology as the mirror on the wall that reflects back to us who we are: we want technology to do things for us; it shows us that we are finite, frail, and mortal, that we create technology in order to bring alternative worlds into being – and that we do not know why we create or according to what values, and thus, we have to discover the reasons and the values. And it shows that we do not agree on these reasons and values. As this mirror reflects the humans, it reflects also God. One just has to recall discussions over transhumanism and the posthuman future in its utopian and dystopian versions. These discussions, however, do not cancel our location in technonature. Technology is not something external to us, and theology/religion must encompass both cyborgs and technonature.

Theology of technonature is inherently transdisciplinary, creating connections where things

were previously disconnected or seemed unrelated. It also implies the effort to relate in novel ways and accountability for one’s articulations. It is a quest for a situated knowledge, fuelled by the desire to locate ourselves in our world.

A theology of technonature implies intense intimacy and collapse into each other of the terms “nature” and “culture”; nature and culture are border terms which require explanation and cannot be taken as self-evident “objects over there”; there is no break in the continuum (except those breaks we ourselves determine). A theology of technonature must understand the concerns of the (techno-)culture (e.g., epistemological concerns, environmental crisis, ambiguity of technological advances, the role of desires and imagination) that occasioned the theological response. It has to be in recognizable continuity with Christian tradition (i.e., it is based on more than current cultural preferences), but it has to recognize that technonature is the only place where cyborgs can meet God. In this sense, technology itself has become a sacred space.

Description

The academic study of theater falls into two disciplines. *Theater studies* approaches theater as an art form, focusing on written texts (drama), as well as theater's history, aesthetic conventions, formal characteristics, styles, and genres. Theater studies examines plays and performances from world theatrical traditions such as Japanese Noh

and Kabuki, European fourth-wall realism, Indian dance drama, Beijing opera, and Balinese shadow puppetry. Folk theater and performance art are also objects of study as are hybrid genres such as magic realism, a blend of mystical Chicano folk theater with European realism. Theater studies takes its interpretive methods from humanistic disciplines (history, literature, aesthetic theory, philosophy, and arts criticism). *Performance studies*, a newer discipline, has its roots in anthropology and folklore. Performance studies views theater as a social practice constituted in and by culture. The focus in performance studies is on performance events. J. L. Austin's notion that language is performative (rather than descriptive) is foundational. Performativity is the analytical paradigm through which performance studies interprets events such as sports contests, religious pageants, parades, military displays, political demonstrations, circuses, civic rituals, demonstrations of scientific discoveries, digital performance, and museums. Theater is understood as one mode of performative behavior among many. Performance studies takes its methods from social science disciplines (including anthropology, ethnography, sociology, folklore, and media studies) as well as literary theory, language theory, and cultural studies. Both disciplines can interpret theater's engagement with science and religion.

The academic study of theater and performance does not belong specifically to the fields of science or religion. As practiced in academic departments and institutes for the study of theater, theater and performance studies seek to understand the relationship between theatrical performances and the social worlds in which they function. Plays and performances that reflect the natural world fall in the domain of science; speculations into the supernatural enter the domain of religion. Science and religion are topics for theater and performance scholarship to the extent that plays and performances present observations and speculations in either domain. The remainder of this entry identifies tensions between religion and science in theatrical aesthetics and history as suggested by theater studies and performance studies over the past three decades.

In most world cultures, archaic theater is linked directly to religious practices. Tragedy was performed at the Athenian festival of Dionysus in the fifth century B.C.E., a civic event that invoked the Greek pantheon and Bronze Age legends of the Achaean civilization. Athenian tragedy was systematically analyzed and classified by Aristotle in the *Poetics* (c. 325 B.C.E.), a scientific treatise which became the blueprint for the development of secular theater in the European Renaissance. Sanskrit drama emerged in India in the first century C.E. from temple dances, narrative songs, and storytelling performances of the *Mahabharata*, *Ramayana*, and other sources of legends. The *Natyasastra*, a treatise composed between 200 B.C.E. and 200 C.E. by the sage Bharata, details the spiritual dimension of theater, asserting that it was created by the god Brahma. The *Chronicles of Japan* (712 C.E.) relates a Shinto myth in which one goddess performs for another goddess *kagura*, roughly translated as “entertainment of a god.” Shinto and Buddhist beliefs are evident in the stories performed in Japan during the period of the shoguns. The patronage of the fourteenth-century Ashikaga court produced a highly refined theater, Noh, which became the theater of the elite. The aesthetic and spiritual qualities of Noh theater were described at the time in the *Kadensho* by Zeami Motokiyo. Biblical reenactments of the Christian narrative were performed in European churches, monasteries, and towns from the tenth century until the secular academies reconstructed Athenian tragedy in the fifteenth century. There is no known treatise describing the religious aesthetics of biblical drama. Numerous examples of theatrical traditions with ties to religious ceremony, beliefs, and stories are found worldwide. Many originate in localized religious practices, including shamanism and masked dances. Of the traditions given here as examples, each integrated an altar, shrine, or other religious focal point (Brown 1996; Banham 1998).

Most theatrical styles originating in religious traditions used masks, exaggerated gestures, chant or metered speech, and other means to distinguish theatrical presentation from everyday reality and to depict deities and supernatural

occurrences. Realism, the dominant mode of theatrical representation in Western societies, replicates rather than exaggerates or transforms the material, observable world. The aesthetics of theatrical realism are rooted in both religion and science. In Christianity, the unadorned, unmasked human body had theological and iconographic significance. Medieval theatrical representation followed the theology in its depiction of lived human experience. Medieval religious theater did use symbolism and presented nonhuman characters (devils and angels). However, its mode of representation relied on reconstructing the biblical quotidian in order to reinforce humans’ ongoing interaction with incarnate divinity. This preference for “true to life” theatrical representation persisted through the Renaissance and Enlightenment, severed from its religious origins.

Scientific realism influenced theatrical practice in Europe after about 1860. Theater practitioners responded to discoveries revealed by the scientific method and research in anthropology (“primitive” cultures), biology (bacteria, health conditions, and disease), genetics (evolution, inherited diseases), medicine (addiction), social theory (the asylum), and psychoanalysis (the unconscious). These discoveries opened debates about the influence of society, genetics, social institutions, and evolutionary tendencies on human behavior. The effect was to render nature and human society subject to rational, scientific analysis and to reinforce experimentation and objective observation as methods for arriving at empirical truths. The dissemination of scientific knowledge into popular discourse in the nineteenth century joined scientific realism to an established aesthetic for accurately representing human behavior and emotions. Theater provided a mechanism for reconstructing societies, the physical world, and human behavior for the purpose of observation and analysis.

As medical “theaters” allowed spectators to witness surgical procedures, theatrical stages became “laboratories” for the analysis of human beings. Heinrich Ibsen, August Strindberg, and Emile Zola conceived of theatrical performance and playwriting as experimental procedures for

testing the effects of social and biological conditions on human behavior. Plays could demonstrate how human behavior is the result of people's psychological makeup, genetic inheritance, position in society and environment, and physiological constitution. The conventions of realistic representation were held superior to aesthetics that used symbolism, poetry, religious imagery, and other techniques to evoke the supernatural, religious beliefs, or transcendent experiences.

An evolutionary model in theater history prevailed until the 1980s. In that model, religious theater or ritual was construed as a precursor to modern, realistic theater. The evolutionary model tended to exoticize non-Christian, non-Western, and folk theater grounded in religious belief or spiritual practices. The ritual-to-theater progression was challenged in the 1980s, with the emphasis on how Eurocentric definitions of drama and theater had influenced perceptions of non-Western theater forms. Challenges to the ritual-to-theater model and the dominance of realist aesthetics came from an increasing number of cross-cultural projects, such as Patrice Pavis' edited collection, *The Intercultural Performance Reader* (Routledge 1996), which rejected the perception of nonindustrial cultures and religious theater as "primitive." With the emphasis on multi- and intercultural theater in the 1980s, religious theater and ritual performances gained status as cultural statements.

In theatrical practice, the modernist turn away from religion was counterbalanced by explorations of eastern and folk religions in the early twentieth century. In an effort to preserve or recoup theater's capacity to present spiritual themes, as well as to escape narrowly positivist readings of plays and performances, some Western theater practitioners and scholars sought alternative aesthetics. William Butler Yeats, for example, wrote a series of plays imbued with spiritual themes based on the Japanese Noh drama. Heinrich Ibsen and August Strindberg explored spiritual themes in their symbolist work. Other playwrights invested in realism, such as Eugene O'Neill investigated and were influenced by Asian religious traditions.

After the Second World War, theorists and scholars evinced suspicion of the scientific paradigms that had grounded realism. In the 1960s, amid social unrest in the United States and Europe, critiques of theatrical realism, scientific positivism, and the industrial ends of scientific research opened theater studies to explorations of theater's ritualistic, if not specifically religious, capacities. The study of ritual as performance came into theater studies and performance studies from anthropology with the work of Victor Turner in the 1960s. Richard Schechner's experimental performance piece *Dionysus in '69* (1969), for example, attempted to recuperate ritual as a function of theater. Theater artists such as the Jerzy Grotowski and Peter Brook devised theater styles that infused secular theater with the components of religious rituals from Western and non-Western traditions. These included apotheosis, catharsis, a sense of sacredness, stimulation of the senses, mythologies, and transformed perception (if not religious transcendence).

Postmodern theories were widely deployed in theater studies and performance studies from the 1980s through the early twenty-first century. Postmodern theory denied a unified, verifiable reality that could be represented and held that reality was in fact constructed, deconstructed, and reconstructed by competing systems of representation (language, architecture, and mediatized performance). The goal was to reveal how meaning is socially constructed and supported by hierarchies of power (including those of religious institutions and industries supported by scientific research). Modernism had construed art as an autonomous domain of aesthetics, the emotional effects of which were distinct from the effects of religion. Postmodernism likewise rejected metaphysics along with scientific positivism, scientific progress, and technological utopias in the effort to view all claims to knowledge (scientific or religious) as contingent. Postmodern theories did, however, account for religion, popular religious expression, and internally experienced spirituality as constructed by institutional power and as an axis for identifying cultural difference. In the early twenty-first century, theater and performance

studies have begun to recognize religion as constitutive of social and political identities, along with race, gender, ethnicity, sexuality, culture, and socioeconomic class.

The academic study of theater often separates science and religion, favoring science as a model for inquiry and analysis. In the secular orientation of research universities, the potential for religious traditions to offer epistemological frames for themes, narratives, or theatrical aesthetics has not been prominent. A suspicion of religion's "antitheatrical prejudice," a preference for rigorous science-based analysis, and modernist claims of the autonomy of art also contributed to the tendency to dismiss religion.

Self-identification

Science

Science, as a mode of inquiry dependent on experiment and the quantification of the physical world, is often set against the arts and humanities, which are construed as descriptive, interpretive, and invested in human interaction, social formations, and culture. In theater and performance studies, postmodern theory offered highly technical, specialized vocabularies, theoretical models, and methods for such research, which in many ways emulated scientific discourse. Neither theater studies nor performance studies, however, characteristically employs experimentation or quantitative methods and thus rarely identifies as scientific inquiry. Science and theater are linked in four distinct ways.

1. Science as a guide to theatrical aesthetics. Theatrical practice can respond directly to knowledge derived from science to create new artistic forms. The experimental theater of Robert Wilson and Richard Foreman in the 1970s illustrated broadly accessible scientific concepts such as the general theory of relativity, timeframes intersecting, the relationship between energy and matter, and the uncertainty principle, as well as the "concept" of scientific discovery in the figure of Albert Einstein. Such experiments in form and

content take principles of science to guide the development of nonrepresentational aesthetics. The artists mentioned above deployed computational, algorithmic, and geometric logic as well as principles of modern physics to devise innovative ways of moving objects and organizing stage space.

2. Science plays as a genre. Michael Frayn's 1998 play *Copenhagen*, which dramatizes meetings between Niels Bohr and Werner Heisenberg and explores both the uncertainty principle and complementarity, has been widely noted as emblematic of a new genre of "science plays." These are plays that represent scientific discoveries, lives of scientists, scientific concepts, debates about the uses of science, or the culture of science and scientists. Such plays might offer critiques of science and scientific agendas (Friedrich Dürrenmatt's *The Physicists*, 1962), engage scientific ideas (Tom Stoppard's *Hapgood*, 1988 and *Arcadia*, 1993), present events in the history of science (Bertolt Brecht's *Life of Galileo*, first version c. 1937), examine scientific enterprises and the culture of scientific inquiry as a profession (Stephen Poliakoff's *Blinded by the Sun*, 1966), use science to investigate human relationships (David Auburn's *Proof*, 2001), dramatize the personalities of individual scientists (Peter Parnell's *QED*, 2002), and place science or scientists in imaginary situations (Steve Martin's absurdist comedy, *Picasso at the Lapin Agile*, 1993). Scientists and mathematicians who have turned to playwriting and theatrical performance as a technology for distributing mathematical and scientific ideas include cosmologist, mathematical sciences professor and recipient of the 2006 Templeton Prize for research in religion, John Barrow (*Infinites*, 2002); chemist Carl Djerassi (*An Immaculate Misconception*, 1999 and *Oxygen*, 2001); and biologist Alain Prochiantz (*Biology in the Bedroom*, 1995). Science plays and performance pieces cross genres. Some playwrights, scientists, and performance artists adapt language, dramatic structure, staging requirements, and character interactions so that the play performs the

scientific concepts through its structure (Timberlake Wertenbaker, *After Darwin*, 1998) (Shepherd-Barr 2006). Others are crafted in the conventions of realistic representation and linear narrative.

3. Pedagogy. Playwriting and theatrical performance can be used to foster scientific literacy. Such plays seek to make scientific or mathematical principles accessible and meaningful by putting them in the context of human experience. They generally engage audiences in general or simplified concepts rather than present specific formulas, calculations, or experimental designs. For example, the PULSE Initiative, a result of research at the Centre for Applied Theatre Research at the University of Manchester (2002) and funded by the Wellcome Trust's public engagement effort, uses theater in service of scientific literacy. Performance studies would include museum exhibits, "science shows," planetarium displays, science fairs, public demonstrations of scientific anomalies, and scientific experiments themselves as a kind of theater (See Barbacci 2005).
4. Theater technology. Science and theatrical practice intersect in theater technology. Lighting, sound, set, and costume design rely on research in optics, computer science, mechanical and electrical engineering, robotics, textiles, acoustics, and electronics. Innovations such as DMX512 (digital programming for movable lights, hydraulics, and other stage effects), first developed in 1986 by the Engineering Commission of United States Institute for Theatre Technology (USITT), are the result of artistic and commercial theater collaborating with applied sciences and industry. Interpretive methods used in theater and performance studies, such as semiology and aesthetics, are sometimes referred to as "science." They are not, however, experimental nor do they test theories using empirical measures. "Science" here refers to analysis of performances as phenomena.

Religion

Religion, as a mode of knowing, seeks a transcendent reality or truth. Religious truth is not proven

by experimentation but is revealed by signs or texts, expressed in ritual, and verified by subjective experience (spirituality) or belief. In practice, theater can engage similar affective domains of human consciousness as religious experience (wonder, insights, strong emotions, feelings of being transported beyond mind and body). The work of Nina P. Azari argues for a neurological difference between emotions recorded in the limbic brain and sensations identified as spiritual. In work such as that of Ralph Yarrow, "sacred" is identified not with emotions but with states of consciousness (*Sacred Theatre*, Intellect Books, 2008). The modernist rejection of transcendence in art and suspicion of facile, bourgeois religious sentimentality still operates in theater and performance theory, despite postmodernism's high tolerance for ambiguity. Religion and theater are, however, linked in four distinct ways.

1. Reinforcement of belief tradition or cultural artifact. Reconstructions of Sanskrit drama, Noh plays, forms of Chinese opera, Athenian tragedies, and medieval European passion plays reference the religious traditions in which they emerged historically of their origins. They may or may not assume that performers, and audiences share the religious beliefs depicted. Some dramatic performances, such as Easter pageants performed in Christian churches, use drama to reinforce religious beliefs shared by performers and audiences. Theatrical rituals, ritualized theater, and theater that expresses religious beliefs are performed today all over the world. In a religious context, they are defined by function (propitiation, commemoration, invocation, cultivation of mystical experience, healing, magic). Genres may include storytelling and praise poetry recitations, shamanic ceremonies, spiritual masquerades, masked dance dramas, reenactments of myths, healing ceremonies, and impersonation of deities. Korean masked folk plays, Tibetan monastic drama, North American Easter dramas, and African shaman ceremonies serve as examples of theatrical forms serving religious functions. These types of performances support the notion that theater and religion are coextensive in practice, or at

least analogous. “Sacred theater” is sometimes construed as a therapeutic practice.

2. Religion as object. Commercial theater has engaged religion outside a ritual or religious context. Large-scale, successful musical productions include *Jesus Christ Superstar* (Tim Rice and Andrew Lloyd Webber, 1972) and *Godspell* (Stephen Schwartz and John-Michael Tebelak, 1973). Both musicals set Christian narratives with contemporary language, costuming, and music and were highly successful. Terrence McNally’s 1998 play *Corpus Christi* took a similarly updated approach but used theater to challenge Christian dogma by presenting biblical figures as homosexual characters. *Corpus Christi*’s challenge to Christian heteronormativity was controversial, and the play received harsh criticism from the Anglican Church and other Christian groups.
3. Pedagogy. Theater can serve pedagogical purposes beyond reinforcing a particular belief system. One such isolated example is James Still’s *A Long Bridge Over Deep Waters* (Toni Weingarten, “Theater Seeks Common Ground for Intersecting Faiths,” *The New York Times*, June 11, 2005). This drama takes as its topic religion in a heterogeneous society and documents ten religious groups in Los Angeles. In 2005, the production was part of a 5-year initiative by the Los Angeles Cornerstone Theater Company to use theater to foster interreligious understanding. The play’s performance in the John Anson Ford Amphitheater challenged a 1964 prohibition against religious performance in a public county venue. Another example is the work of Nicholas Bhekifa Mamba whose activist theater addresses how systems of religious beliefs differ and how those differences can affect attitudes toward the disease itself, AIDS, polygamy, homosexuality, and gender hierarchies. Mr. Mamba was a lecturer and featured participant in class conversations at the Yale Divinity School in the spring of 2009 (<http://www.yaledailynews.com/articles/view/28386>).
4. Implicit religion and spirituality. Some secular theatrical traditions aim to evoke feelings

associated with religious or spiritual experience (unity, sense of divinity, wonder, glimpses of an ineffable reality) or speculations associated with religious quests (meaning, morality, existence of a guiding power influencing human actions, free will). These can fall into the domain of *implicit religion*. Ritualistic theater practices developed in the 1960s, the European symbolist movement of the 1930s, Peter Brook’s notion of “holy theater,” and post-World War II existentialist theater, are examples from Western theater theory and practice.

Characteristics

The study of theater and performance is distinctive in that it applies interpretive frameworks and methods of analysis to cultural practices that are themselves interpretive and reflective. Theater and performance studies engage in meta-analysis or meta-critique in the effort to understand how and why people perform and what meanings performances have in and beyond their contexts. Whereas sciences and religions seek ultimate truths, the study of theater and performance seeks the truths or questions a performance seeks to present and how the performance communicates that (scientific or religious) truth.

Relevance to Science and Religion

The last decade has seen an increase in the number of plays dealing with science. Renewed interest in religion since 2001 has prompted scholars to seek religious influences on playwrights, to examine performance practices such as outdoor pageants, and to reexamine the relationship between theater and religious expression. Plays that dramatize the collision of science and religion, such as Jerome Lawrence and Robert Edwin Lee’s realistic *Inherit the Wind* (1955) and Bertolt Brecht’s epic *Life of Galileo* (first version c. 1937), suggest that theater studies and performance studies can participate in the larger discourse on the interplay between science

and religion and that theater practitioners can find ways to take up aspects of cultural debates through the medium of performance.

Sources of Authority

The comprehensive and definitive study of science plays is Kirsten Shepherd-Barr's *Science on Stage: From Doctor Faustus to Copenhagen* (Princeton: Princeton University Press, 2006). Shepherd-Barr includes an annotated, categorized list of science plays written over the past 400 years with cogent discussions of how these plays and performances engage science. Performance studies has been influenced by Robert P. Crease's 1993 monograph, *The Play of Nature: Experimentation as Performance* (Bloomington: Indiana University Press), which uses a theatrical model to examine the phenomenon of scientific experimentation, scientific discovery as Aristotelian *anagnorisis*, narrative processes at work in developing scientific theory, the laboratory as stage, and performativity in the culture of scientific practice.

New journals, *Ecumenica: A Journal of Theater and Performance*, *The Journal of Religion and Theatre*, and *Performance and Spirituality*, provide outlets for the study of religion and theater. These journals have helped overcome the notion that religious theater is an evolutionary precursor to secular theater, inherently conservative, or characteristic of non-Western or ancient cultures. The Association for Theatre in Higher Education focus group, Religion and Theater, has helped overcome biases against bringing religion into academic discussions. Richard Schechner's *Between Theatre and Anthropology* (1985) remains the foundation for studies of ritual and performance. Schechner's analysis of cross-cultural performance covers a wide range of ritual performance practices, the annual Yaqui Easter pageant in Arizona, Balinese trance performance Ramlila of Ramnagar, tourist performances at Plimoth Plantation, and ritual theater. Richard Schechner's definition of performance as "twice behaved" or "restored" behavior gives religious rituals and performances equal place with secular,

artistic theater. An increasing willingness to investigate religion as an epistemological foundation for theater is evident in books such as *Theatre and Religion on Krishna's Stage: Performing in Vrindavan* by David V. Mason (New York: Palgrave MacMillan, 2009).

Ethical Principles

Performance studies, which often requires interactive field work, follows the ethical principles set out in the subdisciplines of anthropology and ethnography. Field work is subject to institutional review board approval, which protects human subjects. As with documentary filmmaking, participant observation methods account for the effects of the researcher's presence.

Key Values

The core value of both theater studies and performance studies is making explicit the means and meanings of human social activity. Both disciplines focus on activity that is intended to elicit response and which requires conscious display. Performance is construed as material and accessible to the senses, embodying truths but not truth itself.

Conceptualization

In the last three decades, theater and performance scholarship has regarded concepts such as truth, knowledge, nature, ontologies and teleologies, the notion of "human," and reality as products of social and cultural forces. Their meaning is not considered to be transparent.

Nature/World

Theater as a practice is generally thought to reflect aspects of the social world and to depict human emotions and relationships. Because theater deals primarily with human narratives, nature appears as a theme rather than an object for representation. Theater is construed not as

a Cartesian mirror of nature but as a method by which fragments of situated perceptions of nature are refracted and contested.

Human

Human experience is at the center of most plays and theatrical performances. The aestheticized depiction of human decisions, struggles, adventures, passions, relationships with others, ordeals, and other kinds of experiences allows observers to make connections between events represented theatrically and “real” life.

Life and Death

The work of American theater scholar and practitioner Herbert Blau offers insights into the complexities of theatrical representation with regard to life and death. Theater creates ephemeral characters, places, and worlds. These die, metaphorically, when the performance ends. Conversely, whatever reality the performance displaces in the process of representing it also dies as soon as the materiality of the performance displaces it. Herbert Blau’s influential work, in particular *Take up the Bodies: Theatre at the Vanishing Point* (Urbana: University of Illinois Press, 1982), posits life and death as subjects represented in narratives about human experience and as the condition of theater itself. It is the thought of death that prompts the corporeal act of theater and the awareness of life from which theater emerges. Theater is a physical means of confronting death as an unknown (Kubiak 2004).

Reality

Theatrical artifice can create visual, aural, and tactile worlds that appear to alter the laws of physical realities proven by science. Theater can also depict imaginary realities described by religious myths and texts in which, for example, animals speak, objects fly through the air of their own accord, and dead people speak with the living. Insofar as theater reflects the interplay between the physical world and human experience, its mechanisms of artifice can defy, challenge, reinforce, critique, or interpret the truth claims of both science and religion.

Knowledge

In practice, theater rarely presents as discourse the intricacies of scientific and mathematical problem-solving, which results in new knowledge about how the world works. Theater can reinforce religious beliefs, demonstrate the resolution of religious conundrums, or generate feeling that can ground a kind of knowledge about the world. The modality is evocative rather than discursive. Theater reflects and refracts existing knowledge of humans’ relationship to the natural and supernatural worlds.

Truth

Science and religion seek to make and represent accurate truth claims. Theater, in contrast, relies on artifice, metaphor, simile, and approximation to present perspectives on truth. Western realistic theater, though modeled on practices and ideas drawn from the sciences, disguises the artifice and can appear to present truth directly. Insofar, as both science and religion seek to understand and articulate ultimate, universal truths, theater’s inherent artifice produces a tension between truth and its presentation.

Perception

Theater has the capacity to alter perception. Many theatrical styles present an exaggerated or fantastical reality through stylized or symbolic gesture vocabularies, elaborate costumes and makeup, heightened or poetic speech, designated performance spaces, manipulation of time and space, and vocal techniques such as chant or pitched speech. Theater can also use technologies of performance (curtained stage, fixed seating, props, sets, artificial lighting) so that observers perceive stage action as “real life.” An intense emotional or intellectual release of tension, theater produces a shift in perception called, from Aristotle, catharsis.

Time

Narrative theater can reverse chronologies, move back and forth in time, represent multiple time frames simultaneously, and alter the perception of time (“stage time” vs. “real time”). Studies of plays such as August Strindberg’s *Dreamplay*,

Tony Kushner's *Angels in America*, or Tom Stoppard's *Arcadia* (referenced above) require analysis of shifting time frames and the relation of stage time to real time.

Consciousness

Consciousness is a vast subject for theater and performance. Theater may attempt to represent the complex and illogical workings of human consciousness visually as in the work of Richard Foreman and in August Strindberg's 1901 exploration of dream consciousness, *Dreamplay*. Shakespeare's *Hamlet* (1603) could also be considered an example of a play working out a character's logical, linear consciousness, whereas Tony Kushner's *Angels in America: A Gay Fantasy on National Themes* (1990) shows characters, such as the mentally disturbed Harper, who experience and speak from fragmented, disjointed consciousness. Acting training emphasizes performers' consciousness in a wide variety of ways: conscious emotional and physical unity with a character (American "method" acting), cultivating a meditative state (Noh theater), mind/body consciousness and presence (Suzuki technique), expression of corporeal consciousness (Butoh dance drama) are some examples. For some theater practitioners, the performance itself should transform an audience's consciousness through shocking visual imagery and sensory stimuli. For Western practitioners and scholars, Asian consciousness has offered an alternative mode of consciousness. Two studies are foundational. *Staging Consciousness: Theatre and the Materialization of Mind* by William Demastes (University of Michigan Press, 2002) takes theater as the meeting point between mind and the material world. This study rejects Cartesian dualism and analyzes a variety of plays and performances to show consciousness as fluid, nonlinear, and multivalent. In *Theatre and Consciousness: Explanatory Scope and Future Potential* (Bristol, UK: Intellect Books, 2005), Daniel Meyer-Dinkgrafe covers aspects of consciousness and theater including inspiration, creative process, representation of consciousness, acting, audience reception, Indian theater

aesthetics, and Western interpretations of Hindu consciousness.

Rationality/Reason

The modernist rift between religion and art is linked historically to the turn toward scientific rationalism and causality in the eighteenth century. The Kantian idea that aesthetic judgments are objective, rational, and universal is articulated in the *Critique of Reason* (1790). By the mid-twentieth century, the aesthetic theory of Theodor Adorno reiterated the problem of transcendence and interrogated notions of universal beauty. Postmodern theory regards theater as a material process distinct from any transcendent or supernatural reality. In this philosophical trajectory, emotional response is thought to be subject to reason or constituted by social and cultural forces.

Mystery

Theater and performance scholarship influenced by postmodernism emphasizes the displacement of "the real" in sequences of signifying images produced by the dramatic text or performance event. Notions of an inner self, undiscovered knowledge, truth, or mystery, are considered imagined or constructed fantasies. Peter Brook's influential *The Empty Space* (1968) identified "holy theater" as that which makes the invisible visible, the mysterious known.

Relevant Themes

In the last 20 years, the study of theater and performance has combined analysis of texts with analysis of performances situated in culture and history. Much scholarly work has been done on theater as a refraction of human behavior, societies, perceptions, and consciousness. Studies of corporeality, the body, embodiment, and agency continue to emphasize optics, semiotics, and visual signification. As a corporeal practice distinct from film and other reproducible media, performance (including ritual) elicits and produces physiological responses without attention to the biological body. Neuroscience,

neurotheology, and cognitive science can be joined to philosophies of corporeality, embodiment, and agency to better understand why religious narratives and ideas are given expression in the corporeal form of theater across a wide range of cultures. Such studies need not be reductionist or narrowly materialist.

Theism, Classical

Anders Kraal

Department of Philosophy, University of British Columbia, Vancouver, BC, Canada

Related Terms

[Orthodox theism](#); [Perfect being theology](#); [Traditional theism](#)

God has been conceived of differently in different religious and philosophical traditions. The term “classical theism” is often used in philosophy of religion textbooks to designate a way of conceiving of God that is standard in historical Christianity and is expressed in the writings of major Christian theologians, for example, Augustine of Hippo’s *The City of God* (1998) and Thomas Aquinas’s *Summa Theologica* (1948). According to this conception, God is the perfect being, which means or entails that God is, among other things, necessarily existent, eternal, changeless, almighty, all-knowing, supremely good, distinct from creation, and the creator of everything distinct from himself. God is also said to be absolutely simple, which means that the above-listed attributes are identical to God’s being and, more generally, that there is no ontological complexity in God.

Classical theists also conceive of God as triune, as Father, Son, and Holy Spirit: three persons but one being. But since the term “classical theism” is used almost exclusively in the context of natural theology as opposed to revealed theology (or in the context of philosophy of religion as opposed to systematic theology), Trinitarian doctrines are rarely cited in discussions of classical theism.

When classical theism is understood in the above way, it contrasts with conceptions of God associated with, for example, pantheism's claim that God and creation are nondistinct, process theology's claim that God can undergo change, open theism's claim that God does not know all future events, and the claims of various liberal theologians to the effect that God is not a being with attributes. There is disagreement, moreover, as to whether prominent analytic theists such as Nicholas Wolterstorff and Alvin Plantinga are properly describable as classical theists. The evidence goes both ways. On the one hand, these philosophers see themselves as traditional Christians and at odds with various modern theologies. On the other hand, their quest for philosophical coherency has sometimes led to substantial revisions of and even departures from key classical theistic doctrines. Thus Wolterstorff (1975) rejects Divine eternality in the classical sense, and Plantinga (1980) rejects absolute simplicity. In view of these and other departures from the classical tradition, some authors, such as Brian Davies (2004), deny that the above thinkers are classical theists. Others, such as Michael Peterson et al. (1991), tend to regard them as classical theists but delimit the list of Divine attributes a classical theist need subscribe to (the resulting list is often taken to include only Divine almightiness, all-knowing, and moral perfection). A problem with the latter strategy is to show that such delimitations are not *ad hoc*.

A further question concerns whether non-Christian monotheistic religions such as traditional Sunni Islam are properly describable as classical theistic. Since traditional Sunni Islam, following the school of al-Ashari, rejects absolute simplicity, not to mention the doctrine of the Trinity, it seems that this is not the case. If, however, the list of Divine attributes a classical theist must subscribe to is limited to, say, almightiness, all-knowing, and moral perfection, the answer should be affirmative. But one has then of course subtracted something essential from historical Christianity's conception of God.

Theistic Naturalism

Christopher C. Knight
 ISSR Office, Bene't House, St. Edmund's
 College, Mount Pleasant, Cambridge, UK

“Theistic naturalism” is a term used to label an approach to divine action in which theistic belief is upheld but descriptions of events that invoke divine interference with the world are rejected. Historically, theistic naturalism is associated primarily with the deism of the eighteenth century, in which God was seen as little more than the world's designer, and both miracles and the efficacy of intercessory prayer were denied. More recently, however, other kinds of theistic naturalism have been proposed.

One of these reflects classical deism insofar as any kind of temporal divine interference with the world is denied, but it differs from deism because the way in which it has been expressed – in terms of a “single act” account of divine action or of a distinction between primary and secondary causes – has seemed to some to allow for a broader scope to divine action than classical deism was able to acknowledge. However, this kind of scheme has seemed problematical to many for a number of reasons. One is that it still seems to posit the “absentee landlord” of the deistic understanding. Another is that the model, by itself, has no specific answers to the questions of how God’s will is brought about through natural causes and of what the scope of this mode of divine action might be. A third is that – even in its more specific forms – the model raises questions that have usually been answered only inadequately. When expressed in terms of primary and secondary causes, for example, the model has been seen as mixing levels of description illegitimately, and as denying the reality of contingency and free will.

As a result of problems of this sort, a second kind of approach to divine action represents the majority position within the current dialogue of science and theology. This has relied on a conceptual scheme, which speaks of God acting in a way that is analogous, in many respects, to the way in which any other personal agent acts. In this understanding, a clear distinction is made between “general” providence, which arises straightforwardly from what a benignly designed cosmos will do “on its own,” and what will happen if God chooses to “respond” to events in the world, bringing about an event of “special” providence by interfering with those workings. This interference need not, according to many of the contemporary advocates of special providence, invoke supernatural intervention. Instead, they claim, it simply requires some kind of “causal joint,” which allows God a way of manipulating the processes of the natural world without setting those processes aside.

Some advocates of this approach have put great emphasis on general providence, especially

in relation to the cosmos’s physical development and to the evolutionary history of life on our planet. They have also, in their exploration of the “causal joint” model, made great efforts to propose plausible candidates for this causal joint, so as to emphasize that the laws of nature are never broken in events of special providence, but are instead manipulated in a way consistent with the nondeterministic understanding of modern science. Because of this stress on naturalistic processes, this approach has sometimes been seen as a form of theistic naturalism, and one of its advocates, Arthur Peacocke, has chosen to label himself quite explicitly as a “theistic naturalist.” (Clayton and Peacocke 2007).

However, it is important to recognize that what is envisaged by Peacocke, and by others who pursue this causal joint understanding, is not the kind of “strong” theistic naturalism in which it is held that there is no temporal divine interference with the world. Advocates of this kind of model insist, at least implicitly, that there are two possible outcomes to any situation. One is that which will occur if general providence alone is involved – that is, if God simply continues to sustain the world and the laws of nature obeyed by its components. The other is that which will happen if God – seen here at least implicitly as a temporal being – chooses to “respond” to the situation in the world at any given time (for example, to the need to communicate with his creatures).

The subtle form of divine interference that is envisaged here – in which the laws of nature are not set aside, as in traditional models that invoke the supernatural, but rather are used by God as tools – has led some to speak of this model as a “noninterventionist” one. However, while no event is seen by this model as involving a breach of the laws of nature, and so does not envisage supernatural intervention in the same way as did late medieval models, the way in which the cosmos sometimes follows one path rather than another is seen in this approach as being due to a choice that God has made about whether or not to “respond” to a particular situation, in order to bring about an event of special

providence. This temporal divine response thus represents, for this approach, a causal factor in events of special providence, and as such constitutes interference with the world. The fact that those who advocate causal joint schemes sometimes adopt the “noninterventionist” label, to indicate that they are no longer speaking of supernatural intervention, is therefore potentially misleading, as is the “theistic naturalism” label that Peacocke has adopted – unless, that is, it is qualified by an appropriate adjective. The causal joint approach represents, at most, what we might call a “weak” theistic naturalism, very different to the kind of “strong” theistic naturalism in which any sort of temporal divine interference is denied.

The reason that defenders of causal joint models reject the strong version of theistic naturalism is, most commonly, that they identify it with the deism of the eighteenth century, in which the scope of general providence is seen as extremely limited. It is arguable, however, that the limitations assumed by classical deism are not intrinsic to a purely naturalistic approach, which, in itself, assumes simply that the cosmos develops according to “fixed instructions” of a law-like kind. The possibility that such instructions can, by themselves, bring about subtle and appropriate “responses” to events in the world cannot be precluded in principle. As Christopher C. Knight (2007) has argued in his book, *The God of Nature*, not only can we conjecture specific naturalistic mechanisms for providential “response” to needs, but we must also recognize that the possibility of a nondeistic strong theistic naturalism does not depend on the validity of any particular mechanisms that may be suggested in this way. It depends, rather, on acceptance of the general belief that lies behind the search for such mechanisms (and also behind many of the arguments about emergent levels of complexity that have arisen in the context of recent debate about reductionism.) This belief is that the inbuilt “fixed instructions” of the created order are far more subtle and complex than our present scientific understanding indicates. Once this is accepted as a possibility, it follows that

a strong theistic naturalism can in principle be constructed in such a way that the scope of divine action is not limited in the way that the deists assumed.

One of the main objections sometimes voiced to a strong theistic naturalism is that it must envisage the essentially “absent” God of the deistic model. However, this is only true if we accept the separation of God from the world that has characterized most Western philosophical theology, and ignore the force of the arguments that have been used to challenge this concept of separation in recent years. Panentheism – the notion that the cosmos is to be seen as being in some sense “in God” – is in fact finding increasing favor from a number of different perspectives, and if a panentheistic position is adopted, the argument about an “absent” God immediately fails, for if the cosmos is within God’s self, then God can hardly be said to be absent from it. In this sense, it is ironic that a panentheistic understanding has been advocated by many – including Arthur Peacocke and Philip Clayton (2007) – who have also defended a causal joint understanding of special divine action; for, by taking up a panentheistic position, they undermine what might otherwise have been a major argument against the sort of strong theistic naturalism that they oppose.

Knight’s own panentheistic proposal is based in part on strands of Eastern patristic and Byzantine theology. We can, he suggests, avoid a deistic restriction on the scope of divine action without recourse to either supernaturalist or causal joint thinking, by reviving and revising the concept of teleology. This is possible, he argues, through a consideration of the scientific factors that are relevant to current discussion of the anthropic cosmological principle and of the predictability of biological evolution. Just as it is possible for Simon Conway Morris (2003) – in his book *Life’s Solution*, – to talk about “evolutionary convergence” in terms of predictable, functional solutions to problems of adaptation – “attractors” “analogous to those in chaos theory – so here teleology is understood, not as in medieval philosophy, but in similar terms to those that Conway Morris has outlined.

The interaction of chance and the laws of nature is such, it would seem, that certain developmental paths are in practice very likely to be followed, and these “attractors” may, in a theological perspective, be explicitly understood as a component of the God’s design of the universe.

Through this kind of neo-teleology, it may be argued, we can speak of an intended final end while avoiding the sort of quasi-vitalistic framework in which the components of the universe are seen as being drawn toward that end by some external agent or force. “Attractors,” in the sense in which Conway Morris uses the term, do not literally attract through some kind of force or influence that they exert. They are simply likely outcomes of laws of nature acting on the components of the universe, and may be understood, scientifically, in terms that make no reference to these outcomes themselves. We may, in a theological context, choose to speak of the reality of these attractors in terms of God’s design of the entire universe, but, if we do this, it is important to recognize that the tendencies we identify as part of the divine design are, at the level of scientific description, still absolutely intrinsic to the components of the universe and to the laws that they obey. Theological interpretation of these tendencies in no way impinges on their scientific description, so that the notion of God’s design of the cosmos is quite different here to that envisaged by the advocates of so-called Intelligent Design.

Theistic naturalism has, then, moved far beyond its deistic roots in recent years. While some theistic naturalists still argue for an approach that tends to limit the scope of divine action in a deistic way, others – either through a causal joint or a neo-teleological approach – argue that a rejection of supernatural causality does not limit divine action in the way that the deists assumed. The advocates of causal joint explanation – implicitly assuming a temporal model of God’s being and rejecting the traditional notion of God’s nontemporal character – insist that we can still speak of special providence as well as acknowledging the kind of general providence to which deistic thought limits itself. By contrast, recent developments of the

neo-teleological approach, while rejecting special providence, suggest that we can develop an understanding of general providence that is far richer than either the deists or advocates of special providence have recognized. All events that have previously been attributed to special providence may, according to this latter view, be seen as due to God’s general providence, so that a strong theistic naturalism can be adopted without denying the historicity or possibility of “miraculous” events. God’s involvement in the world is not denied in this approach, but is interpreted in terms of a panentheism that is compatible with the traditional notion of God’s nontemporal character.

Theological Anthropology

Lluís Oviedo

Pontifical University Antonianum, Roma, Italy

Description

Theological anthropology (TA) is a part of theology dealing with the Christian understanding of human beings. It is a modern invention, resulting from the coming together of two former treatises present in traditional theological curricula: humans as created beings and original sin, and the meaning and influence of grace. The new synthesis follows the “anthropological turn” that took place at the end of the nineteenth century and emphasizes the central role of human beings in the understanding of religious faith. All the formerly scattered treatises concerning the person have been brought together in an attempt to signify the centrality that is now attributed to humans and their role in the religious process, which was previously excessively focused on the reality of God or the “objective religious dimension.”

The present content of the discipline is quite standardized. The first part deals with humans as created beings in the image and likeness of God; this first section – also called “fundamental TA” – describes the personal traits which better reflect this human condition: the ► [soul](#), ► [freedom](#), rationality, and ► [love](#). The second part deals with the hard issue of “original sin” or the negative dimension of human beings, a strongly disputed field related to the problem of evil. The third part deals with the question of ► [grace](#) or divine, positive, and regenerative power that is a consequence of the process of redemption. As a result of it, people are called to a new life grounded in ► [faith](#), ► [hope](#), and ► [love](#).

Theological anthropology has been one of the most disputed fields in modern theology. Christian denominations have arisen and diversified along the lines of distinct interpretations of anthropological issues, such as the reach of original sin and the effects of grace. These

differences still characterize theological elaborations along confessional lines.

TA has been an established discipline for some time now, within the traditional theological pattern. A first influence with impact on the discipline has been the reception of new philosophical anthropologies, matured during the twentieth century: existentialism, phenomenology, and particularly the ones stressing openness and dependence on others – “otherness.” More socially driven philosophies have weighed in strongly in the field. Some psychological developments were adopted on a small scale (e.g., psychoanalysis and other more humanistic disciplines). Other developments take into account the connections with alternative representations of the human being in different religious traditions (Ward 1999).

Things have changed in a radical way in recent years, especially as a result of contact with science. Several issues have been called into question and have undergone a deep revision, as the Christian view of humans should take into account the discoveries of paleoanthropology, evolutionist biology, genetics, behaviorist, and cognitive sciences. It is possible to understand the present state of TA as a field of fertile reception and discernment of scientific inputs, where several theologians develop their original proposals, often outside confessional divides (Philip Hefner, Nancy Murphy, Wentzel Van Huyssteen, Philip Clayton).

Self-Identification

Science

TA will not be identified as a “science” so long as confessional theologies do not apply scientific standards in their methods. Nevertheless, TA (as well as some brands of theology) intends to become more “scientifically oriented” because its subject matter – the human being – lends himself to observation and experiment. We could even say that TA is one theological subdiscipline in a good position to become better adapted to scientific standards. Three main reasons can be provided for this: firstly, its statements are easily

subjected to empirical testing, as aspects of humans are directly observable; secondly, it is easier to incorporate inputs from other scientific disciplines involved in the study of human beings; and thirdly, it is better equipped to go into a truly interdisciplinary dialogue or to provide views readily connected to the wealth of knowledge describing human reality. TA draws together a long historical experience concerning human nature that provides a hermeneutical insight that many other disciplines lack.

However, the deep and confessed dependence on a theological or even confessional framework makes TA into some kind of “enclosed discipline,” unable to rid itself of some basic tenets. TA is better described as a hermeneutical discipline providing an authoritative experienced view, inside the Christian tradition, and capable of engaging in a fruitful dialogue with science and enriching the sometimes very limited perspective adopted by other theories.

Religion

TA is a “reflective aspect of religious tradition.” TA is no object of prayer or religious cult, but a way of rationally engaging with the believer’s experience. In the Christian tradition, at least, theological endeavor is not just a rationalization of what is otherwise experienced at a deeper, nonobjective level, but also an extension of the experience of faith achieved by other means. In that sense, the aim of theological work is to enable a real experience of God’s ► [revelation](#) and love. However, some theologians may consider this view to be too close to denominational positions and too far removed from scientific endeavor. An alternative way of avoiding such strictures is to undertake “religious studies” – a more neutral or less religiously committed approach – open even to nonbelievers.

As it becomes apparent from the former descriptions, theology in general and TA in particular may be conceived as being half way between the two extremes represented by a scientific discipline and a subjective religious experience. Ideally, TA attempts to strike a good balance between the two above extremes, while

attempting to incorporate the best aspects of both. The real question is how realistic such a program can be.

Characteristics

What makes TA more distinctive is that it is, at the same time, a very theological discipline (one of the main topics in the theology curriculum), and one that is more sensitive to scientific developments. This approach is thereby transferred into the field of theology; TA deals with humans in relation to God, while other theological treatments have precise objectives. TA’s distinctiveness concerns its status and method too: on the one hand, TA is a discipline subject to the principle of revelation (i.e., to truths we access through a scriptural tradition); on the other hand, it needs to consider human experience and perception. Over the years, this has often occurred, when theologians have tried to combine what they had learned from biblical scholarship with what they were experiencing in their own life or through historical developments. The cases of Augustine, Luther, Pascal, or Kierkegaard are good examples of this struggle to account for both: a fixed corpus of ancestral wisdom and the experienced reality of one’s own world and relationships. In each of the above cases, it is possible to identify new important developments that result when this interaction is articulated and delivers deep insights of historical relevance and unsurpassed value.

Relevance to Science and Religion

As mentioned above, TA is very involved in the area of “science and religion,” together with theological cosmology, the scientific study of religion, and the methodological issues concerning truth and meaning. The interest lies in the possibility of deepening and updating the traditional Christian doctrines about human nature and meaning. Many of these traditional views were originally framed inside a

mythological (at first) and a metaphysical (subsequently) framework, as these were the available cognitive patterns at the time of the compilation of the Bible or, later, during medieval and early modern developments. The new framework is strongly configured along scientific lines; the unavoidable consequence is a displacement of former insights, still subject to the old mindset, or unable to evolve into the new patterns. One of the primary interests of TA in that dialogue is to provide a more updated account of Christian beliefs, even at the risk of some degree of change.

A second reason of interest concerns the possibility of benefiting from the many scientific developments concerning issues of religious faith and human understanding. TA goes beyond the need for updating its own ideas better to fit the new scientific frame; it draws on inspirations, methods, and contents. Many examples can be provided of how new scientific approaches help improve the understanding of some of the negative dimension of a human being, even from genetic and neurological standpoints; others can assist in the reconstruction of the process of religious faith.

A third reason of interest is to reciprocate, in an intense and sometimes conflictive dialogue with scientific development. There are many issues at stake, and theologians are required to play a conscious role in the recent struggles concerning the definition of human identity and meaning. Science provides a partial view that can never expect to be a “complete theory” and can account only for some dimensions of the very complex human reality, a crossroads of many disciplines, and a much disputed field. TA cannot desert this open field of theoretical confrontation, if it is to vindicate its own perspective and to contribute by its cumulative wisdom.

In its present state, the discipline is opening up more space for areas of study related to “science and theology,” though the attitude varies across the different cultural settings and theological schools, with some of them being more conservative and closed to influence outside their own tradition, while others are prone to cross-fertilization and are not wary of engaging in the dialogue. A lot depends on how theology’s

relationship with science is conceived. Usually, the conflictive model is less frequent in theology or divinity faculties, but the so-called “incommensurability” model has very often isolated theology from science and developed a model of TA devoid of that concern.

At the opposite end of the scale are those who are too inclined to submit to science-based interpretations. A happy medium should be sought, in order to achieve a more fruitful and mutually critical approach.

Sources of Authority

The most authoritative sources for TA are those of Christian revelation, the Bible and the developments of Christian tradition, as codified in normative texts of recognized authority: the statements of councils and Popes, the liturgical rites and practice, the most outstanding theologians, etc. There is not an explicit canon of authors or sources, but a broad consensus reigns among many theologians concerning the value of works or thinkers which constitute landmarks in the discipline: some are ancient, as Irenaeus and Augustine; some medieval, as Thomas Aquinas, Bonaventure, and Scotus; some reformers, as Luther and Calvin; some modern, as Pascal, Schleiermacher, and Kierkegaard; and finally, some are contemporary, as Karl Barth, Karl Rahner, Hans-Urs von Balthasar, and Wolfgang Pannenberg.

Beyond this point and especially with regard to the impact of science, it is hard to establish landmarks or texts of particular significance. A first attempt at listing authors and works relevant for this endeavor could take the following into account: Wolfgang Pannenberg, *Anthropology in Theological Perspective* (1985); Philip Hefner, *The Human Factor* (2000); Wentzel van Huyssteen, *Alone in the World?* (2006); Philip Clayton, *Mind & Emergence* (2004); and Nancey Murphy, *Bodies and Souls, or Spirited Bodies?* (2006).

What makes all these sources authoritative in some way is – as in other disciplines – the consensus they have met with among academics working in the field.

Ethical Principles

The ethical principles guiding TA are the same as in other theoretical disciplines in the theological realm. Indeed, some traits become specific to these disciplines and distinct from other scientific fields. It shares with general science the commitment to truth and the conviction in its expanding character. Furthermore, it is committed to rigorous methods in achieving that goal, in submitting its interpretations to general scrutiny, and in accepting correction, as a result of scientific advancement, in order to increase knowledge for the benefit of humanity. However, the theological dimension of TA is committed to faithful engagement with Church teaching and tradition, to the service of communities of believers and to the deepening of individual faith or religious insight. In particular, TA's commitment to the deep value of the human person (in the image and likeness of God) generates its profoundly ethical aim of supplying an anthropological view that helps to deter any attempt at diminishing man's dignity and special position in the world. A theologian's sense of responsibility, while allowing them to make relatively bold propositions, should keep them wary of causing possible damage to the commonly shared faith. This field of theology is therefore continuously torn between being loyal to the objective search for truth and to the faith shared by the particular community of believers.

Key Values

The key values of TA descend directly from the above-mentioned ethical rules: truth, fidelity, commitment, and openness. Perhaps the present ideal for this discipline is to be able to provide a bridge between science and theology, both dealing with the mysteries and complexities of human beings and both trying to deliver the best available knowledge in order to promote human freedom and dignity. A frequent misunderstanding of TA is to view it as disjoined from such values, which are in line with modern humanism. TA's engagement with science moves from a deep

conviction aimed at helping human beings to flourish and to reach their fullest potential, in line with religious hopes.

Conceptualization

Nature/The World

Nature or the world is the environment where humans exist and develop. From TA's viewpoint, nature is God's work, traditionally defined as "► [creation](#)," and therefore related to God's plan and purpose. It is an axiom of TA that the material world acquires meaning only in relationship to its highest reality: the human person. The idea converges with modern theories, such as "the ► [anthropic principle](#)" or the dependence of the existing cosmos on an intelligence that is capable of understanding it. The Jewish and Christian revelations, stressing the centrality of humans in the creation process, understand the former steps of constitution of an ordered world as the conditions required to serve human nature. Biblical narratives are very clear, as they state the ontological dependency of real world firstly on God and secondly on humans (as some kind of "delegates"; God has entrusted the created world to humans, not for its limitless exploitation but as a mission of stewardship and sustainability, extending God's creativity).

A further way of interpreting nature through TA harks back to an ancient tradition that values it as a second "revelatory book": for those able to realize and deepen its meaning, nature becomes an open textbook, in which the divine reality and intention may be sensed or followed. Thus, nature constitutes a kind of interface between humans and God; God being a transcendent reality, beyond human grasp, nature becomes – as his work and manifestation of his creative plan – an indirect path to reach his presence. This path has been described in many religious traditions, in which nature evokes experiences of awe and wonder and of revelatory content.

Human Being

Human beings are the subject of TA. They are defined by their origin in God, in whose "image

and likeness” they have been created. Despite this optimistic and exultant description, TA introduces a corrective element of realism, assuming a negative dimension, traditionally described as the result of “original sin.” In a sort of dialectical movement of thesis and antithesis (*image of god* and *sinner*), the synthesis is provided by the doctrine of grace, which restores and even improves the original condition, once the weight of sin and negativity have been taken on and redeemed in Christ. Under the effect of grace, the human being may live a new life of faith, hope, and love. At least, this is how the Christian narrative runs: a model to represent and manage the complexity of humans and to answer their deepest needs. From a Christian point of view, humans indeed carry the weight of negativity and evil and need to restore balance in their life through the relationship that Christ can provide.

Human beings are furthermore conceived as free, conscious, able to love, social, and destined to an immortal life after death; these conditions are sometimes hard to test in the light of science.

Life Origins and Death

The origins of life are clearly inscribed in the program of creation already described: life is, in the Biblical tradition, a divine prerogative, as all life comes from God, and He is its author and regulator. This magnificent view is called to adapt to scientific insights, where life is seen as an emergence from chemical processes. Nevertheless, in the new theological model, this is still one step behind the higher emergences of human ► [consciousness](#) and even higher levels pointing to transcendence.

Life being an essential characteristic of humans, biblical accounts better define human flourishing in terms of fullness of life or life affirmation.

TA describes humans in the struggle between life and death, with life representing a sign of the positive (or divine) dimension and death as the symbol of all that is negative (or opposed to the divine). Death is identified as linked to sin or the human negative side. In any case, restoring life means – again in our model – overcoming

death and opening a horizon of transcendent life, providing a higher quality of hope.

Reality

TA does not per se determine a proper representation of reality. In broader terms, there is an inevitable pluralism, both in the way humans are understood and how reality is conceived. The traditional and orthodox model works with a concept of metaphysical realism, as opposed to “idealism” and “constructivism”: humans are real beings in a real world, which provides the basis for knowledge and mediates religious experience. Inside this tradition, reality depends ultimately on God, who gives consistency to the real world, and warrants human existence and knowledge. The traditional system requires this perception, as a condition of theological development. On the other hand, the Christian concept of reality somehow reduces its reach, as the real world (present to us) is deemed a passing one, even a temporary limited thing, which should give way to a definitive and superior form of reality, which is projected into the ► [eschatological](#) realm.

Recent theological developments work with different conceptions of reality, and so, humans may receive a plural qualification; the description of man as “the image of God” is deeply affected. The issue is not only epistemological, but defines how human beings, their world, and God are mutually related.

Knowledge

Knowledge, in TA’s perspective, is not just the best way to represent or provide accurate models of reality, but rather has a “salvific value”: human knowledge should help to improve our understanding of our dependence on God and guide us into the mysteries of human existence, in order to overcome our sinfulness and reach eternal life; it should also improve the human condition in this life, in ones relationship with others. This somehow more pragmatic view links knowledge as a scientific neutral endeavor to knowledge as a kind of wisdom or spiritual insight, so as to lead to an understanding of the limitations and potentials of the human

condition and to receive a positive revelation able to provide lasting hope. However, in this case, as in many others, a clear pluralism may be identified, as long as the theological tradition is divided between optimist and more skeptical (apophatic) positions. At present, the lines may be drawn to separate those who are more confident in the power of rational inquiry (rational theology and foundationalism) and those distrusting it and pointing to exclusive revelation. Hans Frei has tried to better classify these positions in a typology of five models (Frei 1994), describing the different ways that theology relates to standard forms of reason.

Truth

Truth is the result of knowledge and shares its formerly described characteristics and pluralism. A more pragmatic stance (Lindbeck 1984) states that true interpretations of canonical texts should be identified through positive performance at the level of living communities. In a similar fashion, truth should be linked to its heuristic power or could be seen as an attribution of the claims providing the best explanations, aimed at understanding human nature, avoiding shortcomings, ensuring human integrity and dignity, and preserving man's identity as a creature related to God. Truth is linked in any case to testing processes, as the result of historical experience and ongoing observation of what helps humans to flourish and avoids distress and evil. Other views conceive truth in continuity with the scientific objective and tried and tested theories (McGrath 2004). In other cases, truth is deeply linked to scriptural canon, as its only norm (Vanhoozer 2005). And still other theologians stress the value of truth as fallible and ever vulnerable to external criticism, more in line with critical epistemologies (Neville 2006).

Perception

TA has developed a sense of perception as a mix of immediate contact with reality through the senses and inspiration (as an "inspired insight or awareness").

Perception is mediated by faith or inscribed inside a framework of general notions concerning

the order of reality, purpose, and meaning. Perception can hardly be isolated from a set of former experiences and a global orientation conferring sense or placing each percept into a schema or meaningful pattern, which, for TA, means related to God's will or plan.

Perception may be linked to religious experience, as the proper way to perceive God's presence in one's own life. The question of its epistemological value has been much disputed, as several scholars defend its veracity, while others do not deem it worthy of greater significance, since it should be validated through broader processes going beyond the individual experience, and tested by more objective means.

Time

TA shares a common idea of time with general theology: time is assimilated into a history of salvation, a process in which humans experience God's love amid the trials and struggles of life. Time is measured in theological terms as the advancement of God's salvific plan or of its didactic interaction with humans. Besides this, time is limited by the concept of eternity, which belongs to God, and defines the end of time, the eschatological bliss or a transformation of reality, no longer submitted to the logic of time and corruption, but lived in a new condition of freedom from every limitation. Obviously, a theology of time built inside an anthropological framework is much more complex and requires a more phenomenological analysis, as the relationship between time and the promise of eternity prompts a special consciousness and a way to conduct one's life. Authors like Antje Jackelén have explored more thoroughly that dialectic (Jackelén 2005).

Consciousness

Over time and with reflection, TA has developed its own understanding of consciousness. It emerges as a result of introspection, especially in the work of Augustine, and relates to the inner presence of God in human beings. After an appropriate revision of the concept of "soul" in TA, due to recent neurological insights, consciousness seems to be best suited to take on the traditional

concept of soul. Nevertheless, despite this positive outlook, the theological view is rather distant from the modern one, which is more inflationary, and assumes too great a role for consciousness as the key factor in every emancipation or progress. However, it does not lead to espousing the “eliminationist” positions of those who have recently tried to discount this faculty as somewhat secondary or illusory. The Christian view limits the range of consciousness, as it assumes a statute of dependence and limitation. Consciousness appears as the result of an external calling, awakening a sense of self, and is developed in a process of constant interaction. It is limited because of the shortcomings and failings of the human condition, perceived as far removed from any standard of fullness and consequently, requiring restoration. In any case, so long as consciousness takes the place of the old “soul,” it still is a more substantial entity and as a result, can hardly be reduced to the material level. Recent explanations by theologians engaged in the dialogue with science point rather to the soul as a form of “emergence” which cannot be reduced to the material substrate but nevertheless should not be identified as a “spiritual reality,” giving way to forms of dualism that are hard to digest down to standard scientific views (N. Murphy, Ph. Clayton). However, the issue is far from settled, as alternative views claim the unavoidable dualism that is entailed by any substantial view of consciousness. The discussion shows not only the unavoidable pluralism in this area, but the close correspondence with other theological issues, like those concerning a more naturalist vs. transcendental view of the divine. The theological understanding of human nature and its predicaments becomes a plural field, especially when confronted with scientific challenges. Furthermore, taking into account other religious traditions – most notably Buddhism – a still more deflated view of consciousness may be obtained.

Rationality/Reason

In the perspective of TA, reason is traditionally the human trait considered more related to God or the one giving specific content to the

claim of humans as “image and likeness of God.” Sharing with the divine this property, reason has been exalted, at least until modern times, as a faculty that better characterizes human identity and differentiates us from other species. Inside a realistic pattern, reason has played a major role as a faculty able to grasp the meaning of reality, to understand intuitively its divine origin and destiny, and to appreciate the “natural moral law.” Reason is perceived less as a neutral tool providing true knowledge and more as a faculty that enables humans to know God and to make their way toward him. Indeed, classical TA has stressed, in line with ancient Greek wisdom, that reason points us in the right direction, while passions or feelings usually do not. Modern views are more balanced, and reason has lost some of its theological appeal (after the major revival it enjoyed during the Enlightenment). As has been already stated concerning other epistemological issues, pluralism is now the norm; it makes way for distinct positions and generates a richer panoply.

Mystery

Mystery has a double meaning in the realm of TA: one negative, as it is applied to the limitations of our knowledge; one positive, as it opens our mind to dimensions of reality beyond our rational grasp and tuned to higher experiences. Mystery is applied to the reality of human persons so long as we cannot offer a “complete” model of their identity and behavior because of their complexity and unpredictability. To acknowledge the sense of mystery in our approach to humans means at the same time to be called to respect this reality as out of reach of any effort for total control or management, an aspect that further confirms their close relation to the mystery of God. Mystical experience can be accounted as a way to fully acknowledge the place of mystery.

Relevant Themes

Human Origin and Evolution

For many years, TA has been engaged, together with paleoanthropological studies, in the task of

reconstructing the picture of human origins. Once the issue of monogenism was settled, thanks to mitochondrial studies, the biological narrative seems to have been nearer to the theological one, despite the many issues still to be settled. TA accepts the biological representation of human origins as a product of evolution from former existing species. Beyond this point, things are more confused. For example, it is not obvious how this process has proceeded and what has guided it, whether sheer adaptation and survival of the fittest or whether other factors were involved.

We are still a long way away from developing a complete and coherent picture of the evolutionary tree that brings from first hominids to *Homo sapiens*. Nevertheless, the present evolutionary hypothesis is the more convincing. TA tries to see a divine purpose in this long process or at least to interpret its outcome as something that corresponds with the divine will. Perhaps a theory of emergence may bridge the gap between the two: the natural biological theory and the theological view, as it creates room for several interpretations.

Naturalizing human origins and evolution is not, in principle, incompatible with a theological position committed to perceive God's hand and a salvific plan. In any case, every description of that evolution should take into account the fact that once intelligence, symbolic ability, and learning reach a certain critical mass, all the history of human evolution needs to be deeply rethought, and new powerful variables determine that evolution in a sense that escapes the logic of sheer adaptation, promoting a different kind of being, less bounded by biological strictures and endowed with an infinite range of new possibilities and abilities (among them, the prospect to transcend the limits of physical reality). Some of the quoted authors like Wentzel van Huyssteen, Philip Clayton, and Simon C. Morris (2003) have dealt in very inspiring ways with these issues, providing insightful views and alternative ways of dealing with the theological understanding of human beings inside the evolutionary framework. In broad terms, the symbolic capacity, the emergence of superior traits, and the

convergence toward some point are the respective theoretical new grounds offered for further exploration.

Freedom

In TA, freedom has been seen as a human condition among those describing our similarity with God. It has been identified as a capacity to decide one's own line of action, to accept or refuse God's offer. Even if the Reformed tradition has discredited this attribute of human nature, as a consequence of human corruption after original sin, it is still kept as an essential ingredient for the fulfillment of human potential. Modernity has shown several factors weighing down human free will, and biology, genetics, and behaviorist psychology, among others, have produced strong skeptical arguments against it. As a result, a more nuanced view of human freedom emerges, more realistic and situated in a network of influences and levers. TA claims that the true identity of a human person includes free will – as one of its main characteristics, perhaps now more as a call to negotiate with different kinds of conditions: genetic or environmental. Freedom is the outcome of the perceived complexity of factors intervening in human behavior and the consequent high level of contingency.

Love and Altruism

For TA, love is one of the most distinctive traits of human nature, but recent research has highlighted how various forms of love may be explained in naturalistic terms. Affective love (*eros*) has been linked to biological reproductive strategies, and its operation has been explained in chemical terms. Neighbors love (*agape*) finds several biological explanations, pointing to genetic interests (*selfish gene*) or to strategies of cooperation and hence to group fitness. Recent neurological research has shown some dynamics presiding this complex process and its natural avenues. Other studies stress biological, ethological, and cognitive factors influencing forms of love. Surely, all this research helps to improve the understanding of its character but could miss one important point as it ignores some of love's specific human traits in the logic of gratuity,

sacrifice, and gift, which probably require a different theoretical framework. The aim of TA is to show the intrinsic character of love, challenging the logic of sheer self-interest and gain. Love points to a divine experience of gratuity and gift, which loses the greater part of its appeal when reduced to something practical. In this experience, humans express something more specific and unassailable, something that many people deem essential for “a life worth living.”

Sin and Evil

Evil is a part of human perception. A model of a human being would be absolutely inaccurate without dealing with this negative dimension. TA's approach to this is through the issue of “original sin”: some kind of negative dimension whose onset is lost in the remoteness of human origins, some ill-defined “wrong,” which still affects the human condition. Recent research has pointed to some genetic and neurologic traits of human nature, in which violence and an affirmative leaning had been critical for early survival. After humans evolved to become more socially oriented or cooperative, some imbalance weighed down on human beings. Human nature is viewed in a more realistic way, less prone to the idealism of more modern ideologies or naïve anthropologies. Nevertheless, this research does not exactly legitimize the traditional narrative of TA, i.e., the ancient fault of the first ancestors, but rather reveals a kind of unfinished state, something that triggers new theological questions. To date, the best study and presentation of this issue, combining our current biological knowledge and theological insight, is given by Daryl P. Domning and Monika K. Hellwig (2006).

Religion

The scientific study of religion has opened many new paths to the understanding of this human trait, which TA has always identified as an inborn ability for transcendence and for receiving a divine revelation. Things become more complicated as the biological, neurological, and cognitive approaches sometimes try to deconstruct this original proposition and to

show its derivative character (an epiphenomenon) or its adaptive character, at least in an earlier stage of human evolution. TA's present endeavor is to offer a more open picture, taking into account the new research and aiming to restore that human ability as a genuine dimension giving access to true transcendence. “Explaining religion” in natural terms should not mean eliminating it or “explaining it away.”

The Ancient Near Eastern picture of what is deity in relationship to humanity and the rest of the world underwent significant change as the state of Judea became a more or less integrated part of the culture of the Mediterranean empires of Greece and Rome. These changes were largely due to the way Platonic and Aristotelian conceptions of God as a first principle of reality modified the biblical conception of God as the creator of the world. Once absorbed the new rabbinic understanding of theology was further, possibly more radically, modified by the influence of medieval Jewish natural philosophers into what in modern times would be recognized as the traditional or Orthodox doctrine of God. At the core of what emerges as Jewish dogma in this area is a synthesis of Platonic and Aristotelian theology in the light of medieval commentaries, both philosophical and kabbalistic. However, no sooner formalized as foundational doctrine, modern scientific conceptions of the divine radically undercut and thereby challenged not only contemporary belief in God in particular, but other traditional rabbinic so-called dogmas as well. The most serious challenges have arisen from modern physical reductionist interpretation of science in general as well as from modern philosophical interpretations of epistemology under the influence of the new neurosciences. The most difficult points of comparison have to do with the influence of the new cognitive sciences on theories of rational evidence, mathematics on interpretations of infinity, and accounts of causation in all the physical sciences.

At least four issues about the traditional Jewish conception of God can be isolated because of the hegemony of modern mechanist-mathematical science over the premodern Platonic-Aristotelian science of classical Jewish theology. First and most obvious are challenges that arise from modern physical astronomy. Here the most glaring issue turns on the size and age of the universe in connection with traditional doctrine of divine providence. Given what we know about astronomy, how can we understand the traditional claim that God governs the entire universe, both at the level of its smallest components and at the level of its largest components? With specific reference to the largest objects in the universe, at the level of galaxies, what we know calls into question all we thought we knew from medieval Jewish philosophers about the nature of divine control, since in premodern astronomy stars and constellations were viewed as living angelic beings and not just as earth-like rocks or conscious-less cauldrons of fire floating through space.

The second challenge comes from Quantum Mechanics. At the level of the microscopic, the suggestion is that the laws of nature at least at this smallest realm of beings are probability equations. What does this say about traditional claims about the perfection of divine knowledge and God's concern for every creature, no matter how small, since truth in terms of real probabilities is simply reasonable opinion about the future, and probability laws hold for sets of individuals but not for the individuals within the sets. Hence, if Quantum Mechanics provides a correct description of the universe as God created it, then it is hard to understand what it means to claim that God in any sense cares about individuals of any kind, especially about human beings. If the answer is that he does not, then this judgment significantly undercuts the rationale for liberal as opposed to traditional Judaism, since the heart of the development of liberal Judaism lies in the primacy of the value it places on the individual, in contrast to traditional Judaism's emphasis on the primacy of community, i.e., of the collective Jewish people.

The third challenge comes from physics, especially with reference to the principle of

inertia. What is at stake here is the authority of the traditional Aristotelian proofs of the existence of God shared by Jews with Muslims and Christians. Put in its simplest terms, Aristotelian science assumes that the normal state of objects is at rest, so that some cause is needed to account for their activity or change, whereas, specifically because of the principle of inertia, modern physics assumes that the normal state of objects is in motion, so that some cause is needed to account for rest (e.g., friction). This difference goes to the heart of why the traditional proofs of God's existence, whose validity was apparent to premodern natural philosophers, are clearly not persuasive to modern scientists. This distinction might be even more fundamental to the difference between modern and premodern science than the issue of whether teleological, purposeful explanations in contrast to mechanical, mathematical explanations can count in science. The issue is: Do you need a cause of infinite potentiality to account for an infinite number of finite entities and states of affairs? The answer is no, if an effect can be greater than its cause, and it was this affirmation that the premoderns found unintelligible. However, given the principle of inertia, there is no reason why an infinitely long effect or series of effects cannot follow from a distinctly finite cause.

The fourth and final issue relates to the changes from premodern to modern theories of logic and language. Drawing from an Aristotelian account of meaning, all of the classical Jewish (as well as Christian and Muslim) natural philosophers took for granted that what something is given in a definition, a definition predicates at least two attributes (a genus and the specific difference) of the subject, and these attributes are universals that exist within the substance of their subjects. This so-called internal notion of predication becomes especially problematic when speaking about God. The philosopher who highlighted this paradox was Moses Maimonides in his *Guide to the Perplexed*, and his solution, called "negative theology," has dominated Jewish philosophy since the thirteenth century.

Briefly stated, God must be "one" because if he were not he could not be the first cause of

everything in the universe. A first cause is an entity whose existence is dependent only on what the entity itself is. But if there is complexity in the entity, say, for example, that it was defined by two distinctly different attributes, then the first cause would not be first, since as a compound, its existence is determined by its essential components. Consequently, the creator God of the universe, by definition, must be so simple that he has one and only one essential attribute, and that attribute is identical with him. The consequence of this analysis is that in principle, any statement about what God is, when taken literally, says nothing but “God is God” and therefore gives no information. In fact, we can know nothing about whom or what God is; only whom or what God is not. Hence, all meaningful statements about God are equivocal in meaning. What they say about God is what he is not, and what they say positively has only human moral content. So, for example, we do not say that God is ignorant, because ignorance is a human deficiency. Rather we say God is “all-knowing,” because, all factors being equal, knowledge is a human virtue. Hence, the statement “God is all-knowing” says nothing about God. What it says is that God is not ignorant and humans ought to seek wisdom as a virtue.

However, as we have said, negative theology rests on certain assumptions about language, none of which apply to modern non-Aristotelians accounts of meaning. What is most important is that adjectives are not statements of universals that actually exist within substantive subjects. Hence, there is no obvious reason why simple positive statements about God, true or false, cannot be made, and classical Jewish philosophy cannot guide us in how to make them, because of its no longer applicable account of meaning and language.

One consequence of this negative judgment about the implicit semantics behind traditional works of Jewish theology has been to free Jewish theologically and linguistically from the restraints imposed by Maimonides. To be sure, Jewish philosophers continue even in theology to be guided by their rabbinic predecessors, but they are not controlled by them. Hence, for example,

Benedict Spinoza can speak of God in literal, positive terms as an “infinite substance,” while Martin Buber can speak of God within his phenomenological language as “an Eternal Thou,” in radical opposition to Spinoza, for Buber’s deity, while “eternal,” which is comparable to being “infinite,” is in no sense a substance. Similarly, Franz Rosenzweig captures the modern (Whiteheadian) sense of God as the origin and end of all motion while remaining true in some sense to Maimonides’ negative theology when he claims that whatever is not God, so that everything that comes to be defined God by not being him, so that at the end of days God will fully be as what he is not.

[Qur'an](#)

Description

In its formative medieval period, Islamic theology, defined as a systematic discourse about God carried out by Muslims, evolved as part of the premodern world's most internally diverse cultural sphere. The vast territorial range of the religion, combined with its inability to generate an authoritative church-like hierarchy to define and impose doctrine, ensured that acceptable Muslim ways of speaking about the divine evolved over centuries by largely consensual processes, and that no formal list of creedal essentials was ever generally promulgated.

Properly speaking, therefore, there are multiple Islamic theologies, rather than a single discrete tradition with settled canons of orthodoxy. Of these, three have substantially survived in the majoritarian Sunni context: Ash'arism, Maturidism, and Hanbalism, all of which are generally regarded as valid. In the context of Shi'ism (approximately 10% of Muslims), the medieval Mu'tazilite school, rejected in Sunnism, continues to have wide authority.

The unifying principle, however, is invariably the theological content of the Qur'an. The Muslim scripture, seeking to disprove polytheism and to rectify Trinitarian and incarnationist views in Christianity, teaches a radically monotheistic

doctrine. God (Allah) names himself as Compassionate, Loving, Creator, Willer, Guide, Knower, and Raiser of the dead, in a cosmic vision of divine power and providence. Humans are created to love and worship God, and will face a Day of Judgment where God will send sinners to hell and the righteous to eternal reward and to a beatific vision of His face. Salvation is by grace, not works; but the latter are nonetheless seen as hugely important expressions of submission to the Divine will.

The fondness of some Enlightenment thinkers for Islam, which they saw as a rational and non-superstitious faith, has encouraged many modern Muslim theologians to assume that modernity need not impose radical revisions to Islamic metaphysics. However, there have been two major departures from the three classical Sunni schools in the past century: Firstly, a modest revival in Mu'tazilite fortunes on the assumption that Mu'tazilism allows a greater use of reason in interpreting scripture, and that its view of natural causality is hospitable to modern physics. Turkish and Indonesian divinity schools have been most influenced by this trend. Secondly, the movement known as Wahhabism has gained in currency among some thinkers who believe that the medieval incorporation of Greek reason, and traditional pieties surrounding belief in the saints, must be replaced by a return to the literal sense of scripture. In this way, Wahhabism may be compared to the Protestant Reformation.

Self-identification

Science

The terms "science" and "religion" are both Eurocentric and have limited relevance to Islam. Islamic theology does not see itself as a "science" in the European sense. However, it has evolved complex definitions of matter, usually based on a belief in atoms, and discussions of the reality of natural causality that are of scientific relevance. To the extent that arguments from design lie at the center of Muslim arguments for the existence of God and appear in the Qur'an itself, Islamic theology may be said to propose a general system

for the methodical derivation of facts about the material world from first principles, appealing to human observation.

Religion

Islam defines itself with the Arabic word *din*, meaning a transaction between humanity and God. In a general sense, then, Islam is a religion. However, *din* implies not only “religious” aspects of life, such as belief and worship, but an all-encompassing commitment to the Creator, expressed in a sacred law (Sharia) which has no clear equivalent in Christianity, despite resembling canon law in some principles. In this respect, Islam as a religion resembles Judaism more than Christianity.

Characteristics

Islamic theology generally contrasts with non-monotheistic theologies in its insistence on a personal creator God who is close to His creatures and may be approached through prayer. It is distinctive from Judaism in its belief in Jesus as messiah, and in Muhammad as the final prophet (“Seal of the Messengers”), and in its belief that the sharia is a facilitated divine law that replaces the Mosaic code. It differs from Christianity in that it regards the Trinity as compromising the full unity of God (► [Tawhid](#)) and as imposing difficulties on worshippers as they seek to conceptualize the deity. It also rejects the Christian belief in the atoning sacrifice of Christ, holding that God forgives sinners directly, without requiring a substitute or mediator.

Relevance to Science and Religion

Perhaps the commonest apologetic claim in contemporary Islamic theology takes the form of the idea that Islam is the scientific religion *par excellence*. Popular and semipopular writers, such as Maurice Bucaille and Harun Yahya, who seek to show the Qur’an’s compatibility with modern cosmology and embryology, are hugely popular across the Muslim world. Some more

academic theologians have created the genre of al-i‘jaz al-‘ilmi, roughly translated as “scientific apologetic miracle studies,” which seeks to use alleged Qur’anic anticipations of modern science as arguments for the Qur’an’s divine authorship. The quality of this literature is variable, but at its best, it is of genuine intellectual and scientific interest. Journals such as *Islam and Science* try to show the relevance of traditional cosmologies to modern scientific paradigms.

Sources of Authority

God is cited as its sole authority. He is believed to express His qualities and His will through “signs” (Ayat), both in the natural world and in the scriptural revelation of the Qur’an, which is taken to be the literal and uncreated word of God. A further source of revelation is the ► [Hadith](#), documents which record the sayings and acts of the Prophet Muhammad. Reason (‘Aql) is also seen, particularly in late Ash’arism and in Maturidism, as a key source of knowledge about God, and logic is intensively cultivated.

Ethical Principles

Hanbali and Ash’ari theologies typically adopt a “command ethic” approach. Good and evil may be intuited but are authentically known only through revelation. Those unreached by revelation are therefore not subjects of moral judgment. Maturidi and many Shi‘i thinkers hold that moral axioms are intrinsic, and that human natural knowledge of good and evil is sufficient to render us genuine moral agents accountable to God, even in the absence of scripture.

Key Values

The list of virtues and vices is generally shared with the other monotheistic theologies. In contemporary contexts, Islamic values are typically conservative, with a great majority of believers opposing sex before marriage, homosexuality, and some forms of feminism.

Conceptualization

Nature/World

Revered as a complex of signs indicating the qualities of God. There is no concept of original sin.

Human Being

Created to be God's representative on earth, reflecting aspects of the divine nature and called to worship, to marry, to live in families, and to respect the aged.

Life and Death

Most Muslim theologians believe that the Qur'anic account of the origins of life is compatible with science. A controversy over Darwinism exists but is not as salient as in Christianity. Humans originated in the divine presence and will return to it for judgment and (for the blessed) in eternity.

Reality

Material reality, for Ash'aris and many Maturidis, is occasionalistic: particles exist only instantaneously and not continuously. Causality, properly understood, is God's direct action through apparent proximate causes.

Knowledge

Knowledge is to be integrated in a system in which knowledge of God lends meaning to all else and defines the relationship of the sciences. Knowledge may also come through religious experience, and Islam has a complex mystical tradition (► [Sufism](#)).

Truth

This is a Qur'anic name of God. For Muslim theologians, without God, the term is of merely logical or arithmetic value.

Perception

Muslim theology inherited Aristotelian theories of sense-perception and its interpretation by the brain; these are now substantially amended. There can be a direct perception of God in the next world.

Time

Time is part of God's creation; the theologians dispute whether time is a continuum or a series of disconnected moments.

Consciousness

This reposes in the soul (*ruh*) created by God but indestructible in humans.

Rationality/Reason

Muslim theology uses this to prove metaphysical claims and to defend the coherence of doctrines such as resurrection which cannot be proved by reason.

Mystery

The essence of God is "veiled," but there are no formal "mysteries of the faith."

Relevant Themes

The Qur'an's repeated invocation of natural phenomena as signs of God's power and existence ensures that Muslim theology today is closely engaged with science. In general, the simplicity of this system and the absence of mystery ensure a fairly constructive encounter between science and faith for most thinkers.

Theoretical Psychology

Henderikus J. Stam
Department of Psychology, University of
Calgary, Calgary, AB, Canada

Related Terms

[Cognition](#); [Constructionism](#); [Hermeneutics](#);
[Personhood](#); [Psychology](#); [Science](#)

Description

Theoretical psychology (TP) is a subdiscipline as well as a general orientation to psychology. It has come to fruition especially as an expression of post-positivism beginning in the 1960s. It concerns itself with foundational questions in psychology, the application of the philosophy of science to psychological research, and the critique of the social implications of the discipline. Cognitive science and philosophy of mind clearly form one set of interests in TP. In addition, it has branched widely into historical and critical analyses of psychology including those of a critical realist, hermeneutic, feminist, social constructionist, poststructuralist, and postmodernist variety (Gergen 1985; Richardson et al. 1999). Hence, there is no single orientation that describes TP, but, instead, it is a subdiscipline that concerns itself with the critical analysis of psychology as a theoretical enterprise and as a discipline (Robinson 2007).

More recently, TP has concerned itself with the globalization of psychology, the nature of subjectivity as a broad category of analysis, the question of the place of the neurosciences in psychology and the notion of neurophenomenology, the emergence and limitations of such movements as positive psychology and evolutionary psychology, the contemporary expressions of psychoanalysis, and more.

Characteristics

TP is the one subdiscipline that is directly concerned with an overall analysis of the problems and foundations of psychology. It has from time to time critiqued the mainstream, suggested alternative approaches to psychology, or created new fields of inquiry. It also joins with others in psychology, for example, in cognitive science, to discuss, analyze, or engage working scientists in new work. TP often interests itself explicitly in interdisciplinary work by crossing boundaries and working in adjacent fields of sociology, philosophy, anthropology, and so on.

Relevance to Science and Religion

Theoretical psychologists are, in general, sympathetic to an understanding of the relationship between religion and science. Some of these psychologists take this up explicitly in the guise of a relationship between religious aspirations and ethics or in the form of normative considerations as understood in psychology and the religious impulse in human activity. Given TP's general critique of positivism in science, it is also sympathetic to alternative forms of investigation of all human phenomena, including religion. However, TP's critical stance can also apply to religious concerns and the expression of religiosity. In addition, there are many in TP who are not directly interested or concerned with the nature of religious phenomena.

A number of individuals who self-identify as theoretical psychologists hold positions in denominational colleges and universities and hence work explicitly on the relationship between psychology as a science and religious questions, broadly conceived.

Sources of Authority

As a relatively small subdiscipline of psychology, most theoretical psychologists begin their careers with training in another field of psychology. Crucial to TP is the importance of the philosophy of science and either analytic philosophy or continental philosophy of the last approximately 100 years. Some theoretical psychologists take their inspiration from the traditions of Edmund Husserl, Martin Heidegger, Maurice Merleau-Ponty, and Jean-Paul Sartre, whereas others are more enamored with the traditions of Bertrand Russell through Ludwig Wittgenstein, and forward, to contemporary philosophers of science and mind. In addition, there are others who are clearly either informed by various forms of critical theory inspired by such authors as Michel Foucault, Jacques Lacan, or Gilles Deleuze; feminists of various orientations; and cultural theorists. All of this is put to the service of understanding, analyzing, critiquing, or rebuilding psychology, subjectivity, or human activity.

Ethical Principles

On the one hand, ethical principles are somewhat less germane for TP than they are for fields that engage in active research with people or nonhuman animals. Normally theoretical work does not encroach on the private lives of those investigated. However, more broadly conceived moral considerations form part of the traditions of theoretical psychology if only because a number of theoretical psychologists believe that psychology is a "moral science" as that term was used in the nineteenth and early twentieth centuries. That is, essentially human characteristics on this view always entail questions of how we ought to live and hence invoke questions about what constitutes the mores and norms of human life. This is a position that was already well developed in, for example, the work of John Dewey.

Key Values

TP seems to have a critical wing and a more salutary, pedagogic wing. The critical wing of TP has been in existence for some time and, with a long tradition of critique in philosophy and social theory, examines psychology for its covert commitments to individualism and support of the status quo. Sometimes, this wing goes by the name of critical psychology, and it has strong affinities with the Frankfurt School, postmodernism, the work of continental thinkers such as Michel Foucault, second-wave feminism, and the New Left of post World War II. It values criticism and analysis of psychology's social commitments in the name of an emancipatory psychology.

The pedagogic wing of TP is concerned with the analysis of the philosophical commitments of psychology and generally supports the espousal of "good science." In that vein, it is more concerned with an elaboration and elucidation of issues in psychology that can be clarified through the judicious use of the philosophy of science, including such issues as reductionism, determinism, the nature of the mental, and so on (e.g., Kukla 2001).

Conceptualization

Nature/World

Theoretical psychologists are not so much concerned with nature per se as they are with the question of just what constitutes a natural category or if, indeed, it is possible to ever know just what is “natural” about human existence. This is a question about whether it is even within our capacity to distinguish that which is “natural” from the long legacy of evolutionary, social, and historical existence and whether such a question even makes sense. Although not always a concern for theoretical psychologists, it is an ongoing feature of many of the debates that constitute the field.

Human Being

Unlike most of psychology, theoretical psychologists have generally taken a special interest in what it means to be human or with the related question of personhood. The functional orientation of most of psychology, that is, the indeterminate nature of functional categories in psychology (e.g., memory, attention, cognition, personality), does not commit itself to a perspective on what it is to be human. A long history of human science scholarship in philosophy and psychology has led to considerations from Wilhelm Dilthey through Martin Heidegger and into contemporary psychology of just what constitutes human experience, thought, action, and embodied existence. On the other hand, this tradition is also the focus of considerable critique, especially beginning in the 1980s when “liberal humanism” was viewed as Eurocentric and patriarchal. In a related vein, the human/nonhuman distinction has itself been a question of considerable debate as psychology considers just what it is that is unique about the experience of various kinds of species.

Life and Death

The question of life itself is not a special focus of TP, but the nature of death has been a major preoccupation in the existential literatures that have spilled over into psychological debates in the 1960s forward. The manner in which the possibility of death shapes our understanding of

life, or even “the denial of death” in Ernest Becker’s words, continues to be a source of concern precisely because it is knowledge of death, argue some scholars, that makes human beings psychologically unique beings in the world.

Reality

Notably forms of realism and antirealism have been the focus of attention for the past two or three decades in TP. Social constructionism in various forms has taken up an antirealist stance that led to a vigorous defense of realism by both cognitivist and post-Marxist scholars. In recent years, these debates have settled into a truce since neither side appears to have been successful in compelling a change of view among its opponents; furthermore, there have been few if any new arguments.

Knowledge

The creation and dissemination of new knowledge has been a focus of considerable investments in TP. Influenced by the sociology of knowledge and the social studies of science, the question here revolves around the nature of empirical knowledge in psychology and its relationship to socially implicit or explicit agendas for knowledge construction. For example, a long-standing issue is the nature of individualism in psychology, the preference for explanations at the individual level, and how this has limited the possibilities of other forms of knowledge that understand psychological accounts as inherently praxical, collective, and linguistic.

Truth and Perception

The question of truth and perception is related insofar as theories of perception can be divided into “representational” or “direct.” Representational theories of perception have constituted the mainstream in psychology and have frequently been taken as the establishment version of psychological perception. Truthful or accurate knowledge is a matter of inference from representational knowledge; in this case, “truth” is not directly knowable. “Direct” theories of perception, however, have a realist cast and make access to a knowable world a standard feature of their take on perception. Elsewhere in TP, discussions

of “truth” are not much in vogue if only because they are often seen as leading to intransigence and are viewed as essentially irresolvable.

Time

For some theoretical psychologists, time has a special place in their lexicon because of its place in the work of philosopher Martin Heidegger and his influence on existentialism and humanism. Access to the world is through history, never outside it. This has been taken up in various ways in contemporary theory either through a hermeneutic understanding or indirectly via postmodernism.

Consciousness

That consciousness has returned as a topic to psychology with a surprising vigor is now clear. Having made up the core of psychology in the late nineteenth century, it vanished under behaviorism and mid-twentieth century experimental psychology. With the emergence of consciousness as a *biological* and *philosophical* problem in the 1980s and 1990s, psychology has returned to the question of consciousness in order to investigate the problems of cognition in the context of consciousness and brain function. TP has followed suit and is engaged in many of the same debates as philosophers of mind on, for example, such issues as “the hard problem” of first person consciousness.

Rationality/Reason

Neither rationality nor reason has a particularly special location in the work of TP. However, reason remains a feature of cognitive psychology and by association has remained of some interest to theoretical psychologists.

Mystery

With the exception of occasional references to wonder, mystery or the *mysterium tremendum* in the psychology of religion, TP has shied away from approaching these issues. Although reflecting, perhaps, a lack of genuine concern, it is more likely that it reflects psychology’s long inhibition concerning matters religious other than in the most obvious and superficial way (e.g., as demonstrated in survey research).

Relevant Themes

The problems of language generally and the special case of a discursive psychology have been taken up in a major way by TP in recent years. By this is meant the way in which psychological phenomena can be investigated in discourse. Secondly, it claims that some topics in traditional psychology (e.g., attitudes, memory) can be reconceptualized as problems of discourse.

The problem of embodiment has also been taken up of late under a range of influences that have seen a return of the body as a vehicle of expression psychological existence, the site of power, or the foundation of a gendered life (Stam 1998).

[Mentalizing](#); [Mindreading](#); [Theory of mind debate](#); [Theory theory](#)

While all animal species have social capacities, the human species has particular social skills, one of these skills, perhaps the most important, being the capacity to read the minds of others. Humans possess the cognitive capacity to attribute mental states, that is, beliefs, intents, desires, pretending, knowledge, etc., to themselves and others as well as to understand that others have beliefs, desires, and intentions that are different from their own. Human beings have developed the ability to understand other persons as “minded creatures” (Stueber 2006, 1). To put it differently, they understand that others also “see what is in front of them, remember things that happened to them in the past, deliberate about what to do in the future; they can feel pain, be happy, feel depressed, guilty, ashamed, or proud” (Stueber 2006, 1). Furthermore, human beings know that the way people act correlates with the state of mind they are in at the moment of action. Hence, a person knows the state of mind of another person; she can predict (at least to a certain degree) how the other person is going to act in a certain situation. For example, if I know that one of my students is terrified of getting blackouts whenever he has to take an exam and I know he is a very engaged student, I can predict that he probably will take some tranquilizer some hour before the examination takes place.

Understanding, knowing, or predicting other’s minds and action is known as mentalizing or mindreading. In Alvin Goldman’s words, “It is mind thinking about minds” (Goldman 2006, 3). Human beings, it is argued, are mindreaders. Some refer to humans as Machiavellian primates and mean that human beings read other’s minds in order to predict their behaviors and thus to outsmart them. Others maintain that the human capacity to read other minds is innate for survival purpose. There is also a large agreement that empathy is one core capacity of mindreading. (See article on “► [Empathy](#)” by Karsten Stueber in this encyclopedia.)

Reading and understanding one’s own and other’s minds is also referred to as the *Theory of Mind (ToM)*, which, at least originally, is a philosophical theory. The ToM is *folk Psychology* as a theory. Briefly, folk psychology can be

formulated as follows: If x wants y and believes that z is necessary to obtain y , then obviously, x will do z . If you (x) want to give a good lecture (y) and you believe that in order to do this, you need PowerPoint presentations (z), you will create such presentations (z). Philosophically, mindreading consists in first-person and third-person mindreading. First-person mindreading is directly given and non-inferential but vulnerable to first-person modification (which I call *mindwriting*). In relation to other persons, we have the possibility to disguise or fake our states of mind. To put it with philosopher Pierre Jacob's words, relying on the classical view of mindreading held by philosophers as well as psychologists, "[a] first-person mindreading consists in forming a belief about (or in metarepresenting) a psychological state of one's own" (Jacob 2009, 572). Following the classical view of mindreading again, "a task of third-person mindreading consists in forming a belief (or judgment) about (or in metarepresenting) another's psychological state" (Jacob 2009, 572).

Today, the problem of, or rather the complexity involved in mindreading cannot longer be grasped from only one disciplinary angle. On the contrary, at least three disciplines may be recognized as major contributors to the understanding of mindreading, namely, philosophy, psychology, and neuroscience. Philosophy contributes with its theories based on analyses of, reflection on, and argumentation about observations of human behavior. Psychology (social and developmental psychology in particular) contributes with experimental studies concerning how the capacity of mindreading evolves and develops during infancy and childhood. The contribution of the neurosciences exists in findings from studies of brain injuries, lesions, brain deficiencies (e.g., autism), etc. Cognitive neuroscientists have the advantage of having access to brain imaging technologies, which enable them to study the brain-correlations of different aspects of mindreading in healthy people (e.g., disgust, fear). This implies that different methods are applied to answer the following questions:

1. How do people mindread others – that is, attribute mental states to them?
2. How do people mindread themselves?

3. How is the mindreading capacity, or skill, acquired?

4. What are the contents of people's concepts of mental states? How do they conceive the difference between belief and desire, anger and disgust? (Goldman 2006, 21)

In addition:

5. How does the story of mentalizing fit into the larger story of human cognition? What is the cognitive architecture of mentalizing, and how is it related to the architectures of other cognitive domains?

6. What is the relationship between mentalizing and other forms of social cognition? For example, how is it related to empathy and imitation? What is its relationship to clinical problems such as autism and psychopathy?

7. What is the evolutionary story behind human mentalizing? (Goldman 2006, 21)

It becomes obvious that several theories have emerged in order to try to answer these questions.

The Theory Theory of Mind

One of the dominant theories today is the *Theory Theory of Mind (TToM)* or the *Theory Theory Paradigm*. Roughly, according to the advocates of this theory, our capacity of mindreading is entirely dependent of our capacities to theorize. More precisely, that we understand others and ourselves is due to theoretical reasoning and the causal laws of folk psychology.

This theory comes in two main versions: the *Modularity Approach* and the *Child-Scientist View*.

The Modularity Approach

Simon Baron-Cohen outlined four distinct but interrelated mentalizing modules for understanding mindreading, not least for understanding the capacity of mindreading in autistic persons. These modules are part of a general evolutionary psychology approach (Baron-Cohen 1997). A person has to acquire all four modules in order to develop a full-fledged theory of mind.

The first module is called the *Intentionality Detector (ID)*, which is understood as a kind of perceptual device for interpreting motion in terms of goals and desires. The ID module is based on David Premack's idea that goal detection is hard-wired into the human species (Premack and Woodruff 1978). Hence, it is primitive and survival-related, that is, should one approach or avoid the moving agent. Therefore, it is activated whenever there is any perceptual input that might identify something as an agent (with goals and desires), that is, anything with self-propelled motion or anything that makes a non-random sound. However, Baron-Cohen also included inanimate motion (not self-propelled motion) into the picture. Even if this can lead to false interpretations, for the sake of survival, it is better to spot a potential agent and check its desires and goals than to ignore it (Baron-Cohen 1997, 34–35). The intentionality detector is senses-related, namely, vision, touch, and audition. The intentionality detector is similar to what Leslie calls the infant's Theory of Bodies, and even more similar to what he calls ToMM1 (theory of Mind Mechanism, System 1) (Leslie 1994).

The second module is the *Eye-Direction Detector (EDD)*. This module only works through vision and has three functions: *detecting eyes*, *detecting the direction of eyes*, and *interpreting gaze as "seeing."* The first function is activated whenever the EDD detects eye-like stimuli. Two-month-old infants look almost as long at the eyes as at a whole face but look significantly less at other parts of the face (Baron-Cohen 1997, 38–39). The second function can be translated into: "Are these eyes directed at me or at something else?" Six-month-old infants look two to three times longer at a face looking at them than at a face that looks at something else. Furthermore, the infants will smile, because eye contact triggers smiling and positive emotions (Baron-Cohen 1997, 40–41).

The third function includes knowing from experience that eyes can see. From very early on, infants presumably distinguish seeing from not-seeing; or seeing A from seeing B (Baron-Cohen 1997, 42–43).

The third module that has to be in place in order to develop a full-fledged theory of mind is the *Shared-Attention Mechanism (SAM)*. This important module is responsible for *triadic representations*, in other words, the relationship between an agent, the self, and a (third) object or agent. For example, daddy sees I am watching you! This module is a further development of the Eye-Direction Detector. Nine-month-old toddlers begin to use protodeclarative-pointing gestures. For example, the infant points with an outstretched index finger at an object, gazes at it, looks back and forth a few times to the other person in order to make sure that the other person is looking at the same thing (Bates et al. 1979). Hence, the SAM is also related to the Intentionality Detector (Baron-Cohen 1997, 44–50).

The fourth and perhaps the most important module is the *Theory-of-Mind Mechanism (ToMM)*, after Alan Leslie's theory (1994). The function of this module is to employ a theory of mind, that is, to represent the epistemic mental states such as pretending, thinking, knowing, believing, imagining, dreaming, guessing, and deceiving. This is the "agent-attitude-proposition" function. For example, John believes "it is raining" (Baron-Cohen 1997, 51). Leslie calls these *M-representations* (Leslie 1994). M-representations are crucial to the ability to represent epistemic mental states. This is so because, the attitude is directed toward a proposition, and the proposition can be false while the whole M-representation is true. For example, the proposition "it is raining" will be false if it is not raining, but the whole M-Representation can still be true if John actually *believes* it is raining. Hence, the ToMM allows for *referential opacity* (or non-substitutability), which is a key property of epistemic mental states (Baron-Cohen 1997, 52). The second function of the ToMM is to gather all knowledge into a coherent whole in order to make a useful theory of mind, which is needed to be able to interpret social behavior rapidly and flexibly. The epistemic mental state young children come to understand first is "pretending." From the age of 36–48 months, an infant shows additional epistemic states such as knowing, and

that knowing is a product of perception (Pratt and Bryant 1990). At the same age, they come to understand both true and *false beliefs* (Wellman 1990; Perner 1991). They come to understand deception and grow the ability to deceive others (Sodian and Frith 1992; Frith and Frith 1999).

In summary, at the age of 9 months all infants acquire the Intentionality Detector and the basic functions of the Eye-Direction Detector but the only type of representations they are able to make are dyadic. Between the age of 9 and 18 months, the infants master the Shared-Attention Mechanism and hence their representations become triadic. Between the age of 18 months and 4 years, the child develops a Theory of Mind Mechanism (Baron-Cohen 1997, 55–56). Autistic conditioned children do not (or do not fully) develop the ToMM, which is one of the reasons for why they experience difficulties in socializing.

The Child-Scientist Theory

The child-scientist theory dictates that young children's performance on mentalizing task changes over time as a function of changes in their grasp, or understanding of mental concepts. These changes in concepts, or conceptual understanding, reflect successive stages in children's theories of mind. Therefore, mental concepts must be theoretical concepts. Hence, all determinations of the instantiation of mental concepts in both self and others must be inferential in character. Indeed, it is argued that we attribute mental states to others and ourselves by way of analogical inference. Roughly explained, the analogical inference principle is the idea that other human beings are "very like me" (Melzoff and Moore 2007). In the language of logic, we induce the other from ourselves. Simply put, *x* observes *y*, *y* is like *x*, hence *x* understands *y*. This is Andrew Meltzoff's *theory of imitation* in a nutshell (Meltzoff 2005, 56). For instance, several psychologists have observed that when newborns are put in an environment together with other babies, they try to comfort other crying babies by way of motor mimicry (imitation of behavior) and that some even try to capture the attention of their mother in order to lead her attention to the baby

in need (Goleman 1997, 13–26). In other words, baby A sees baby B crying, thinks "baby B is like me. When I cry my mother comforts me, thus baby B needs mother. When I cry mother will come and comfort baby B." Babies from 42 min to 71 h old are perfectly capable of *reproducing or mimicking* facial movements of others. Psychologists observed that the infants perfectly reproduced tongue protrusion and other facial displays modeled before them (Melzoff and Moore 1983, 703).

The Simulation or Empathy Theory

Another theory of mindreading is known as the *Simulation or Empathy Theory (ST or ET)*. The hybrid version of this theory is perhaps the most liberal since it does not exclude that there may be mirror-neuron mechanisms at work in mindreading nor does it exclude the importance of theorizing for that purpose. Nevertheless, paradigm simulation theorists refrain from the idea that we need theories in order to understand our own and others' mental states. The mental process *p* is a mental simulation of the target mental process *P'*. What the advocates of the hybrid and the paradigm version have in common is the assertion that we put ourselves in another person's mental shoes by way of simulation, imagination, and projection (Goldman 2006; Stueber 2006). (See article on the "► [Simulation Theory](#)" by Henrik Bohlin in this encyclopedia.)

The Rationality Theory

The last theory is the *Rationality Theory (RT)*, which argues that human beings are rationalizers. Humans assume that their fellow humans are rational and seek to map their thoughts and choices by means of this rationality postulate. This theory also comes in two versions, namely, a strong (SRT) and a weak version (WRT). In the strong version, attributors will always assign some belief *P* to a target and also assign to her beliefs in all the logical consequences of *P* (Goldman 2006, 55). To cite Daniel Dennett,

“we aspire to rationality and without the myth of our rationality the concepts of belief and desire would be uprooted. Folk psychology, then, is *idealized* in that it produces its predictions and explanations by calculating in a normative system; it predicts what we will believe, desire, and do, by determining what we ought to believe, desire, and do” (Dennett 1987, 52). According to him, to assume that something is an intentional system is to assume that it is rational. Hence, the assumption that *x* believes *p*, *q*, *r* . . . also implies that *x* is supposed to believe what follows from *p*, *q*, *r* If an intentional agent believes the truths of logic, he is also supposed to follow the rules of logic (Goldman 2006, 55).

Weaker forms of the rationality theory are proposed by Edward Stein (among others) (Stein 1996, 133–134). A first variant is that “attributors interpret targets as always conforming to *some* normative principle of reasoning” and the other variant is that “attributors interpret targets as *sometimes* conforming to *some* normative principles of reasoning” (Goldman 2006, 58). Christopher Cherniak would call these proposal variants of a *minimal rationality* (Cherniak 1986). According to him, this line of thinking avoids the problem of inconsistencies in a set of beliefs. The problem is that the theory becomes rather vague (Goldman 2006, 58).

These theories of mind being presented, I want to challenge the reader to find out whether the six questions mentioned above can be answered by way of applying these theories. In my opinion, none of them can tackle all questions. Hence, the remaining quest is: “Which theory is preferable for in order to answer which question?”

Theory of Relativity, The

Russell Stannard
Department of Physics and Astronomy,
Open University, Milton Keynes, UK

The theory was devised by Albert Einstein. It is divided into two parts. The special theory deals with the effects on space and on time of relative motion. It leads to the formulation of spacetime. One of its consequences is that no physical object can be accelerated to a speed exceeding that of light. Another is that matter is a locked-up form of energy, a proportion of which can be released in nuclear reactions, like those taking place in the Sun. The general theory embraces the special theory but also includes the effects on space and time of gravity and accelerated motion. It replaces the notion of gravitational forces with a curved space and leads to the prediction of black holes. The general theory is the model used to describe the universe as a whole.

Theravada Buddhism

Karim Fathi
Viadrina Europe University Frankfurt (Oder),
Berlin, Germany

Theravada (“The School of the Elders,” the most important and only remaining school of the “Hīnayāna” tradition, meaning “The Small Vehicle”) is the oldest surviving Buddhist school and has a widespread following in Sri Lanka and Southeast Asia. Accordingly, it is relatively conservative and generally closer to early Buddhism. Theravada implies meditation techniques like samatha and vipassanā. In Theravada, the individual realization of bodhi (awakening) is the ultimate goal and usually equated with the term “nirvāṇa.” On the contrary, in nondualist Mahāyāna and partly Vajrayāna tradition, nirvāṇa does not stand for complete enlightenment, since it still implies an opposition (saṃsāra).

Thorn of Alterity

Alexander Darius Ornella

Department of Humanities/Religion, University of Hull, Hull, United Kingdom

The idea of the “thorn of alterity” expresses the conviction that alterity (or otherness) is not something that is added to the self or adds to the self. Rather, it denotes a basic characteristic of the self because it is not grounded or founded in or by itself and cannot be thought without the o/Other. It turns against the idea of an autonomous or “glorified” self but refers to the fundamental human experience that one’s own existence is given, unindebted, and not at our disposal. Art, media in general and media art in particular, can sensitize the human being for the alterity or otherness and discuss questions of human existence that are theologically relevant. These questions deal first and foremost with the meaning of human life and the “from where” and “whereto” of human existence. What exactly the o/Other is, if it is another person, or an ultimate reality – often referred to as God – is open to philosophical and theological discourse.

Time According to Relativity Theory

We owe our modern understanding of time to Einstein’s theory of relativity. Einstein showed that two observers in uniform relative motion do not agree about estimates of time nor of distance. For example, an astronaut on a space mission to another planet would disagree with the mission controller as to the time the journey takes and also as to the distance traveled. According to the mission controller, time passes more slowly in the moving space craft than it does on earth. This effect is known as time dilation. At speeds encountered in normal everyday situations, these differences are too small to notice, but at speeds approaching that of light (300,000 km/s), they become noticeable.

These differences can be understood once one abandons the idea that 3-dimensional space and 1-dimensional time are separate entities. Instead they are to be regarded as welded together to form a 4-dimensional ► [space-time](#). As ordinarily perceived, space and time are but projections of that 4-dimensional reality. And just as a 2-dimensional image (a photograph, say) of a 3-dimensional object depends on the viewpoint adopted, so the time interval between two events (the launch and subsequent arrival of the space craft) will depend upon one’s viewpoint – in this case one’s speed.

Though observers disagree over estimates of time and of distance, they do agree about the separation of events in 4-dimensional space-time. For this reason, many physicists are inclined to accept that what is real is space-time; space and time separately are but appearances of that reality.

For further information as to the way time is viewed in relativity theory, see entry ► [Relativity](#).

The Flow of Time

Nothing about space-time changes. It is quite static. For something to change, it must change in time. But space-time is not in time; on the contrary, time is in it. Because of its static

nature, space-time is sometimes referred to as the block universe.

And yet, of course, we are all aware of a *flow of time*. This notion of things changing comes not from the physics of relativity theory, but rather from our conscious awareness of space-time. Consciousness is sometimes described as directing a searchlight beam onto the time axis of the block universe. The point it picks out is what we call the instant “now.” We are consciously aware only of this one instant, and that it is why it is singled out to be special. As far as physics is concerned, however, there is nothing at all special about it; it has no different a status to any other instant of time. No sooner has the searchlight beam of consciousness identified this particular instant of physical time to be labeled “now” than it moves on, in the direction labeled “future” to alight on the next instant of time. And so on.

A “flow” involves a change of something in a given time. The flow of a river is a measure of how much water has passed a chosen point in a given time. But what do we mean by a flow of time? How much time has passed in a given time? That does not make sense. Not unless we are talking about two types of time. How much physical time, as measured on a clock, has elapsed in a given span of internally assessed mental time? That *does* appear to make sense, and gives rise to the idea that we are indeed dealing with two types of “time.”

Physical time belongs to space-time. We measure it with a clock. The mental time of consciousness appears to have its own ways of being measured – or at least of being roughly estimated. If we sit still, with our eyes shut, we cannot see a timepiece, we are still aware of the passage of time. We become aware of how long we have been sitting there with our eyes shut – at least to the extent of knowing whether we have been doing it for a short time or a longer time. We might even hazard an estimate as to how long we have been doing it in terms of seconds and minutes. We can then, on opening our eyes, compare that internal mental estimate with how much time has passed in the physical world according to a reading on a clock. Sometimes we

underestimate the physical time, whereupon we talk of “time flying”; on other occasions (particularly if we are bored), time appears “to drag.”

How we make internal mental estimates of time is not understood. It might have something to do with the progressive fading of distant memories. So if our recollection of an event is somewhat hazy, it is likely to indicate that a significant passage of time has elapsed since then. Another suggestion is that the estimate might be related to how much has happened since the event in question. If, for instance, one knows that one has had many different thoughts, feelings, and emotions since deciding to sit still with one’s eyes closed, then that too is an indication of how much time must have passed in order to accommodate so many mental experiences. Perhaps the mind is unconsciously keeping track of various bodily sensations, such as one’s heart beat or breathing, and these provide quantitative guidance as to how much time has passed. These are but guesses. One simply does not know how we do it.

The Beginning and End of Time?

The universe began with a big bang. Distant clusters of galaxies are still receding from us in the aftermath of that explosion. But the big bang was no ordinary explosion. It did not take place at a given point in space, the debris subsequently spreading out into surrounding space that had previously been unoccupied. There was no space outside the big bang. It is space itself that is expanding and carrying the galaxies along with it – in much the same way as small coins glued to the surface of a balloon would move apart as the balloon was inflated.

It would thus appear that not only would all the contents of the universe be squashed down to a point at the instant of the big bang but also all of space. Space initially had no volume; there was no space. For this reason, it is believed that space came into existence at the instant of the big bang. And not only space. Because of the intimate connection between space and time (seamlessly welded to each other to form space-time), it is

also believed that the instant of the big bang saw the coming into existence of time.

This, however, is not certain. There is a theory called M-theory that envisages that our big bang might have originated out of a previously existing universe. A tiny region of that universe suddenly underwent a rapid expansion called ► [inflation](#) and our own universe came into being. Likewise, a small region of our universe might at some point in the future undergo inflation, giving rise to a further daughter universe. If this scenario is correct, then there would indeed have been time before our big bang. As for the universe that originally spawned our known universe, it too might have originated from an even earlier universe. Indeed, this process of producing universes might go back indefinitely, there being no beginning to the process, and hence no beginning to time.

What of the future? One idea was that the expansion of the universe might come to an end one day. This would require the mutual gravity operating between the receding galaxy clusters to be strong enough to bring them to a halt. Thereafter, they would be drawn together again, resulting in a big crunch and the elimination of the contents of the universe, of space, and of time. It is now known, however, that there is an additional effect at work – a repulsion due to ► [dark energy](#) (a property of space itself). This is actually causing the clusters to accelerate away from each other. The current consensus is that the expansion of the universe will continue indefinitely. This in turn means that time will have no end; it too will continue indefinitely.

The Arrow of Time

We turn now to the ► [arrow of time](#). Imagine that you are viewing a film. It begins with a cloud of dust swooping down upon a pile of rubble lying on the ground. The cloud disappears from sight, and the rubble leaps up into the air spontaneously. It comes together miraculously to form a factory chimney. Flames and smoke are sucked into a hole at its base. The hole seals itself, and we end up with an intact chimney – intact apart from some sticks of dynamite sticking out of its base.

It is, of course, obvious what is going on. Play the film the other way round and we begin with a chimney and dynamite sticks. There is an explosion sending out flames and smoke from the base. The chimney collapses to a pile of rubble, sending up clouds of dust which gradually disperse. Such behavior makes sense. Clearly this is the correct way of playing the film. The fact that we can tell which way the film ought to be played, i.e., which is the correct way to show the direction of time, is called the arrow of time. With regard to any event, we are able to distinguish which other events in the sequence lie in its past, and which in the future of that event.

Or can we? Let us view another film sequence. This time the camera is placed above the center of a snooker table, pointing directly down. Two snooker balls enter the field of vision traveling at the same speed – one from the top of the frame, the other from the bottom. They collide in the middle and go out of frame in opposite directions, left and right respectively. Now the film is shown in reverse. The two balls enter from the sides of the frame left and right, collide in the center, and go out in opposite directions, top and bottom. Which was the correct way to show the film? Provided the balls show no detectable signs of slowing down, it is impossible to tell. Both renditions of the collision look perfectly feasible. There is nothing to choose between them.

What of a third film, this one showing the swing of the pendulum of a grandfather clock: left, right, left, right, etc.? Play it backward and we get right, left, right, left, etc. Again it is impossible to tell which is the correct way to show the film; both alternatives look equally plausible.

So some processes (a chimney collapsing) look all right one way but not the other, whereas others (snooker balls colliding, and a pendulum swinging) do not. The intriguing point is this: Complex objects such as chimneys and rubble are made up of atoms and molecules. If we were able to film two atoms colliding and bouncing off each other (like the snooker balls), we would not be able to tell which was the correct way to show the film. Physicists call this property of fundamental particles ► [time reversal invariance](#). The same would go for a film of an atom vibrating.

Again (as was the case with the vibrating pendulum), there would be nothing to distinguish one direction of time from the other.

So, we have the situation where we put together a whole lot of individual atomic processes – none of which gives us any clue as to the direction of time – and we end up with a chimney sequence where we *do* know the direction of time! Somehow the arrow of time has sneaked its way in. But how?

In fact, there is no mystery. Let us return once more to the snooker table. Earlier we described a pair of balls coming into view from the top and bottom of the frame, colliding in the middle, and exiting left and right (or it might just as well have been the other way round – we could not tell). We continue to watch the film. A second pair of balls enters, this time from opposite corners of the frame. They exit left and right. They are followed by further pairs, coming in from random directions, but always leaving left and right – exactly. An odd coincidence? It seems as though something is “sucking” them out along those left-right directions. But in reality, we know of no such behavior.

Now we play the sequence in reverse. This time the balls enter left and right, along the exact same paths, and then leave in random directions. This *does* make sense. We deduce that there are two players positioned out of shot, one to the left and the other to the right. They are deliberately aiming the balls at each other, which then scatter randomly. From this we learn that it is possible to take a whole collection of events, none of which individually contains any information on the direction of time but, from the way the events *are oriented relative to each other*, we can get to know the direction of time. It is not that the reverse sequence is impossible. A relative orientation such that the balls come from random directions and all end up going in the same direction is clearly possible, but unlikely – highly unlikely. It is simply that an orientation of collisions the other way round is more probable.

And this is what is happening at the atomic and molecular level during the chimney sequence. It is far, far more likely that atoms, at the start, in the shape of a chimney plus sticks of dynamite, will

end up as rubble and dust, than the other way round. Nevertheless, the reverse is possible. It has to be. Time reversal invariance guarantees that.

The fact that time has an arrow is where the ► [second law of thermodynamics](#) comes in. There are various ways of expressing this law, but essentially it is saying that disorder increases with time. A chimney is an ordered state of matter; a higgledy-piggledy pile of rubble is not. Because of the degree of order, there are relatively few orientations of the bricks that would constitute a recognizable chimney. On the other hand there is a vast – indeed limitless – number of orientations of the bricks that would make up a disordered pile of rubble. Suppose we are shown two photographs, one showing a chimney, and the other a pile of rubble, and are asked which came first. We know that one of the relatively rare combinations of atoms known as “a chimney” is much more likely to end up as one of the limitless number of combinations known as “a pile of rubble,” than the other way round. If one started out with one of the combinations known as “a pile of rubble,” that would almost certainly be succeeded by one of the other many combinations known as “a pile of rubble” rather than by one of the rare combinations known as “a chimney.”

But you might argue that disordered piles of bricks do sometimes become chimneys. True. But this tends to happen only in the case of *open systems* – meaning only for situations that are open to influence from outside. In the present case, it is the outside influence of construction workers. The second law of thermodynamics applies only to *closed systems* where one takes into account all relevant factors. The bricks and cement do not assemble themselves into a chimney. It is done with the help of builders. The builders use up energy. The energy comes from the breakdown of food and the conversion of oxygen into carbon dioxide through breathing. The food was grown with the help of an input of energy from the Sun. The dissipation of heat and light from the Sun is a process causing a great increase in disorder. (This can be readily appreciated if you were to think of the reverse: heat and light scattered randomly throughout space all converging by chance, in an orderly fashion,

onto a single location – the Sun.) Thus, to arrive at an effectively closed system – one to which the second law can legitimately be applied – we must take all these factors into account, including what is happening to the Sun. Once we have done that, we can rest assured that *overall* the second law has been obeyed and there has been a net increase in disorder. As long as the overall closed system operates in accordance with the law, localized increases in order, such as the building of a chimney, are permitted.

How does this second law of thermodynamics fit in with the block universe idea? The law is often stated in the form: Disorder increases with time. So, does that not imply the dynamic passage of time? No it does not. All that the second law tells us is there is more disorder toward one end of the time axis (that labeled “later,” and having, by convention, the higher values of the time coordinates), than there is toward the other end (the one labeled “earlier,” and having the lower values). But that in itself does not require that we mentally experience events sequentially in the direction toward the end labeled “later,” rather than the reverse. The second law is solely concerned with describing the physics of the situation – and in particular that the time axis is asymmetric as regards order and disorder, not how a conscious being might perceive it.

A Smallest Unit of Time?

We divide up time into ever smaller intervals: years, months, weeks, days, hours, minutes, seconds, milliseconds, and so on. But is time infinitesimally divisible, or is there a smallest unit of time? Do we eventually get to a basic unit of time that is no longer capable of subdivision?

At present we have two great physical theories: quantum theory and general relativity. The eventual aim is to reconcile these two into a combined theory of quantum gravity. Such a theory is bound to depend very heavily on three fundamental constants: (1) the gravitational constant, G , governing the strength of gravity in both Newton’s theory of gravity and Einstein’s general theory of relativity; (2) Planck’s constant,

h , governing the size of quantum fluctuations, and (3) the speed of light, c , which figures prominently in both relativistic and quantum physics. If there were to be a smallest division of time, then it is expected that there would be some formula for it. And such a formula would involve these three fundamental constants. Using these constants, the German physicist Max Planck, one of the founders of quantum theory, found that there was a unique way of using them to define a quantity with the dimensions of time:

$$t_P = (hG/2\pi c^5)^{1/2} \approx 5.3 \times 10^{-44} \text{ s}$$

This is named the ► **Planck time**. It is expected that, apart from some unimportant small numerical factor, this would broadly speaking be the form of expression for the smallest unit of time – assuming there were such a thing. Unfortunately, the Planck time is almost inconceivably small compared to any time interval that has ever been measured, or is ever likely to be measured. The shortest time interval measured is 10^{-16} s – a factor 10^{27} bigger than the Planck time. It therefore appears that the question of whether there exists a smallest unit of time is likely to remain unresolved.

Time and Religion

The idea that there might not have been time before the universe had been created is not new. St Augustine reached that conclusion long before today’s cosmologists. Augustine, of course, knew nothing about the big bang nor about space and time forming a 4-dimensional space-time, such that one could neither have space without time nor time without space – and hence the argument that if space originated with the big bang, so might time also.

Instead he argued along the following lines: How do we know there is such a thing as time? It is because things change in time. If nothing changed, or had ever changed, would we know what “time” was? No. It would be a meaningless concept. *A fortiori*, if there were no things at all, changing or otherwise, because they had not been

created, the concept “time” would indeed be devoid of meaning. In this simple way, Augustine recognized that time was as much a property of the world as anything else and hence would have had to have been created along with everything else. Thus Augustine did not believe in a God who had always existed, and then at some particular point in time decided to create a universe.

Turning to our modern-day understanding of how the universe came into being, and God’s role in this, we are not to regard God as the cause of the big bang. Cause follows effect. In this context, the effect is the big bang, so its cause must have occurred before the instant of the big bang. But where the big bang is concerned, there is no before. Thus it is meaningless to talk of it having a cause. It was this that led Stephen Hawking in his best-seller *A Brief History of Time* to pose the rhetorical question “What place then for a creator?”

In doing so, Hawking is confusing two words which, although in everyday conversation might be used interchangeably, in theological discussion they acquire their own distinctive meanings. The words are “origins” and “creation.” The former is all to do with how things got started – how the universe originated. This leads to a consideration of the big bang, and as such, comes within the province of the scientist. The creation question on the other hand is altogether different: “Why is there something rather than nothing?” It is to do with the ultimate reason as to why anything exists. It is as much concerned with existence at the present instant as at the first instant. It is concerned with what is keeping us in existence. In the phrase coined by the theologian Paul Tillich, God is The Ground of All Being. And because this is seen as a continuing activity on God’s part, rather than a one-off action at the beginning, theologians tend to refer to God not only as the Creator, but also as the Sustainer of the world.

Such then are reflections arising out of the possibility of there being no time before the big bang. But what if M-theory is correct, and there was not only time before our own particular big bang, but universes and their daughter universes stretch back in time indefinitely so there was no beginning nor end to this process? Would that get rid of the need for a Creator God? Hawking, in his

later book, *The Grand Design*, thinks so. In it he claims to have now answered the question “Why is there something rather than nothing?” His answer? M-theory. But, of course, that merely raises the question “Why M-theory?” Why indeed are there any laws of nature? Why is the world intelligible rather than being chaotic, with anything and everything happening? Might it not have taken an Intelligence to put it all in place?

Finally, various thoughts with a bearing on theological matters are prompted by the idea of a block universe. These are dealt with under the entry ► [Relativity](#), to which you are referred.

Time Reversal Invariance

Russell Stannard
Department of Physics and Astronomy,
Open University, Milton Keynes, UK

This refers to a fundamental symmetry of the laws of motion, such that reversing the motions of a set of objects leads to a possible state of motion. For example, if one considers the motions of a pair of colliding subatomic particles to be reversed, we would get another example of a possible collision. A video showing the vibration of a pendulum looks perfectly natural whether it is shown normally or on rewind. The fact that usually when a recording is played backward it

looks strange is because we generally observe a complicated system moving from a highly ordered state to one that is disordered (in accordance with the second law of thermodynamics).

Transcendence and Immanence

Iveta Leitane
Department of Philosophy, University of Cologne Research Associate, Cologne, Germany

Transcendence is a philosophical and theological concept of an ultimate origin or instance that is separated by an ontological gap from what it “causes,” “releases” from itself, or brings into being (Szlezák 2002). Usually, it is the difference between the “world” and the “otherworldly” principle or personal being that this term implies. What is transcendent cannot be at anybody’s free disposal so that one might even say that transcendence does not let itself to be defined. The opposite of transcendence is the concept of immanence: where the foundational origin is not something separate from the “world” but is contained and present within it. Transcendence is a term denoting (Szlezák 2002) this absolute

difference, (Worringer 1953) this “otherworldly” principle itself, and (Nicolis and Prigogine 1977) the activity of a limited being or even a person through which it goes beyond its nature. The latter is called a transcending act. There are no simply entirely transcendent or immanent religions. The main question is what in a certain philosophy or religion transcends what and whether and how this act of transcending affects or even changes the agent/subject and the transcendent being or principle itself. Even a religion with a strong sense of transcendence should make the latter in one or another way accessible (and so immanent), and all the issue is what the chances and limits of this approaching are. The term “transcendence” is used in theology, philosophy, anthropology (it is not supposed to have a specific religious meaning here), and mathematics (transcendent numbers). Pre-Socratic thought and late Hellenistic philosophy are immanentists. Anaxagoras’ talk of separation of the *nous* (intellect) from all things might be regarded as approaching the idea of transcendence. The concept of transcendence is developed in Plato in two steps. First, souls emerge from the cosmos to contemplate the “super-heavenly place,” i.e., they transcend the world of the senses through the vision of ideas (Phdr 247bc). Secondly, in the hierarchically ordered world of ideas, an ascent takes place in stages to the presuppositionless “principle of all,” i.e., to the idea of the good, which is distinguished from other ideas by the fact that it is no longer *ousía*, “being,” “but extends beyond the being in rank and power” (Resp. 509, 511b, 517b). There have been debates about the ontological qualification of this “beyond,” namely, should it be understood as gradual “surpassing” of other ideas by the idea of the good or by means of a minimalist interpretation pointing out the absolute otherness of the idea of the good. According to Plato’s *Timaeus*, God is another term for the world soul whose body is the entire cosmos of non-divine things and persons, which can be seen as an explicitly immanentist trait. Forms in Platonic philosophy are immanent (present in many instances) and transcendent (separate from them), and the former implying the latter, there is coincidence of both. The paradigm

is transcendent to and immanent in images of the forms. The properties of the instances are appearances of transcendent forms. The transcendence of forms is but priority of intelligible reality in relation to sensible appearance of that reality. Forms being in instances as their properties imply both transcendence and immanence, and instances being images of the form imply both as well. Transcendent idea is present in all the instances as their determining character. Aristotle applies the phrase “extends far beyond in power and rank” with relation to the Platonic idea of the good to the intellect (*nous*), which for him is not yet “beyond” *ousía*. He contemplated the question of whether God might be “something beyond the *nous*.” The “otherworldly” principle was kept alive in Neopythagoreanism and gnosis, both of which were ultimately inspired by Plato; for Pythagoras, the divine order is immanent in the cosmos and may be encountered there; for Plato, the purified intellect is needed to have access to transcendent metaphysics of forms. The possibility to know the deep structure of the world was guaranteed for Pythagoreanism and Platonism by mind’s essential kinship with its archetypal structure. The notion of transcendence was significantly developed by Plotinus. The soul transcends the world of the senses toward the *nous*; in transcending the *nous* itself, the One can be comprehended as the origin of being, living, and thinking. It remains nevertheless inexpressible in words. This experience of the absolute overcomes the duality of that which thinks and that which is thought while also eliminating the boundaries of the self. This kind of experience offers a basis for some sorts of mystical ascending and ecstasy. Proclus maintains gradualism in this ascending by distinguishing between the relative transcendence of the higher hypostases and the lower and the absolute transcendence of the One (Procl. *Theologia Platonica* 2,5). For the Christian Middle Ages, Pseudo-Dionysius Areopagita, who was influenced by Proclus, was the most important exponent of the concept of transcendence, and since then, the negative theology developed by him has been acknowledged as mostly favoring transcendent traits. Later Neoplatonists enhanced immanentist traits,

believing that there are correspondences between microcosm and macrocosm; they, if properly invoked, would allow them to dispose of psychic energy immanent in the living universe (or its lower strata). This practice of ritual magic, called “theurgy,” is representative for Jewish mysticism as well and rather emphasizes an immanentist view of reality, for transcendence does not lend itself to manipulation. Jewish cabalists would assume that there is a profound affinity between a name and the entity it designates, a phenomenon that is given the name of linguistic immanence. Thus, the one who knows how to decode the Torah as the blueprint of nature can manipulate the physical environment.

The term transcendence is traditionally used in Western religious tradition and emphatically stressed in Protestantism, Judaism, and Islam. The question whether non-European religions are transcendent or immanent lies completely within the Western frame of reference and is more difficult to answer because it depends on the use of other relevant termini in non-Western religions. However, some scholars found this questioning reasonable, especially for comparative purposes and in the context of modern religious dialogue so that some identification with the one (transcendence) or another (immanence) category has been established for some non-European religions by now. Nevertheless, these attitudes lack sophisticated explications of relationship between the two terms so typical in Western theologies and metaphysics. Also, it has to be shown how to translate “transcendence” into other more appropriate terms for those religions. In a very broad sense, any deity can be regarded as transcending human nature and thus “transcendent.” Reality’s transcending (status) with regard to illusion is emphasized in Upanishads. “Transcendence” holds (more generally) as the source of authority merely by its “higher” status. Faith might be seen as “transcending” any state of consciousness. In Daoism and Shintoism – and arguably Buddhism and Confucianism – divinity is said to be rather immanent than transcendent and human beings at one with divinity or the natural world. The

concept of the Buddha in Mahayana presumes that he is no longer merely the person who attained enlightenment in the sixth century BCE but is regarded as a self-manifestation in the history of the *dharmakaya*, a cosmic principle immanent in all beings, the ground of all expressions of the eternal Buddha nature. These descriptions are meaningful as long as one accepts juxtapositions like “human”–“superhuman” correlative to “natural”–“supernatural.” The meaning of transcendence as gradual surpassing of the present state is also evident here as long as we speak of ever-more-transcendent states of Buddhahood, when a sixth supreme Buddha is placed above the set of five cosmic Buddhas. In Buddhist (Tibetan) tradition, transcendence might mean one of the stages in meditative concentration which is not the highest yet (unsurpassable enlightenment). (The transitional character of transcendent characteristics might explain why this term is used even for religious conversions.) In Buddhism, emptiness is also an affirmation of the immanence of the sacred. However, the empty throne icon in early Buddhist art directed the viewer’s attention toward transcendence (Tanaka), and the same was the case with Nabatean tradition where divinity was presented by a niche within a niche, a void within a void (Patrich) that points to something approaching transcendence. Daoist, Buddhist, and Confucian religions represent orientation of the individual toward the transcendent Way, the Dao; the Dao is transcendent in that it is regarded as the supreme wellspring of creativity for heaven, earth, and humanity, but it is also immanent within all life as the vital power (*de*) that informs the nature (*xing*) of each of the myriad beings (*wanwu*). Visnu in Hinduism has been sometimes characterized as one, i.e., transcendent deity having many local varying forms. Aurobindo’s yoga reaches out the divine not through nature but as transcendent to nature. This question gets even more complicated with regard to preliterate religions. In so far as the High God (Supreme Being) is present in these societies, transcendence cannot be completely ruled out. In Australian indigenous tradition, the concept of dreaming can be understood as the transcendent aspect

that keeps connected all key elements of the cosmos. The questions of transcendence and immanence are always (cor)relational to those of monotheism and polytheism (see ► [Polytheism](#); ► [Monotheism](#)). So in Egyptian monotheism, Amun was worshipped as the transcendental creator, existing independently of the world he had created; this characteristic is encapsulated in his name, which means hidden. For example, Zulu's beliefs about God indicate that God is both a transcendent and immanent being who controls the universe and is responsible for all things and all human affairs (Bongmba). African religions combine principles of unity (see ► [Monism](#)) and multiplicity and transcendence and immanence into a single system, and they generally contain both monotheistic and polytheistic aspects without too much pondering about the problematical aspects in this relationship between both (different) features. Roughly, the supreme beings, which remain in the background of religious life, are rather transcendent; the lesser divinities and spirits are bound up with everyday experience remaining immanent, and their relation to human beings is reciprocal and interdependent. Sometimes, heavenly deities are called transcendent whereas earthly ones immanent. The term in the context of non-European religions might mean "otherworldly" and "other-timely" (primordial time in Eliade, primordial, impersonal realm of consciousness in Jung) instances, beings, or principles as well. A central idea shared by most if not all indigenous traditions is that "country" is sacred and imbued with the powerful and immanent spirits of ancestors as transcendent beings. Different kinds of nationalisms which badly needed transcendent features revived these ideas, making an attempt to integrate them into their systems of legitimation. Here also belongs the tendency of European theorists to find transcendence in non-European religions as soon as whenever their own Western civilization is described in mainly immanent terms. Worringer in the 1920s confessed that "we are all the less familiar with the connections that exist between a state of soul which thus inclines toward transcendentalism, and the form of its expression in art," "for

which we lack the organ of understanding," namely, to grasp it as the activity of the form-determining will, rooted in a "quite diverse psychic function," "remote from all reverent affirmation of the phenomenal world," namely, in the "need for redemption" (Worringer 1953). Art as an expression of transcendent feeling shifts the picture of things into a zone of the necessary and abstract that is defined to be an absolute. The interdependence of man and the outside world which gave rise to the "transcendental humor" in Classical Western art has been underplayed in Orient because it evoked agonizing feelings of dependence. To give expression to the transcendent means to de-organize the organic. Not surprisingly was the crystalline form evoked which hinted to hard, abstract forms and imperishable values. The replacement of laws governing the inorganic by the laws that govern the human spirit led to the fact that the ground for transcendent art in the West was lost. In science, scientific striving for knowledge took over this transcendent volition of the old art, and this new art is immanent, a "mild harmony of the living being" in aftermath of the primitivistic transcendentalism. The transcendental was perceived there as heavily enhancing the feeling of dependence (up to enslaving) in the modern subject that was at best seen as something ambivalent.

Within the framework of the above-mentioned questioning about transcendence in non-Western religions, it is considered that the religions of the ancient Near East made a gradual transition from immanence to transcendence in parallel with a transition from polytheism to monotheism. For example, Mesopotamian deity Baal represented the divine power that is immanent in the world, activating and effectuating things or phenomena. The underlying concept of the Priestly Code was the immanent presence of Israel's God in the tabernacle of the congregation, the establishment of the expiatory cult of offerings at the altar, and, along with the cult, the priest's office ministered by the Aaronites at Mount Sinai. The Old Testament indicates that the tabernacle and the temple were considered to have

a transcendent blueprint. Yet already the Deuteronomy Code grasps God in explicitly transcendent terms.

The next crucial and widely discussed question has been the possibility of transcendence in Western societies in Modern age and its relationship with emergent modern science. After the very transcendentalist Middle Ages, Enlightenment intellectuals propounded the “Idea of Progress,” a dogma about the immanence as the substantiation for progressive change. An idea emerged that modernity no longer includes transcendent concerns and is eminently immanentist, remaining nevertheless in one way or another associated with earlier transcendent patterns by means of immanentizing or secularizing them. The common background idea for scholars like Karl Loewith, Eric Voegelin, Norman Cohn, and Jacob Taubes was that Joachim of Fiore with his Three Ages theory stating the supremacy of the kingdom of Holy Spirit imbued with spirit of love and justice started a process in which Christian eschatology was “immanentized” (Voegelin) or “secularized” (Loewith), or it was even declared that “immanence directs itself polemically against theological transcendence” (Carl Schmitt). The four authors recognized the transformation of Christian eschatology into ideologies of inner-worldly progress as the decisive formative power of modernity. Blumenberg stressed that eschatology presuming a break-in of a transcendent event from heterogeneous sources into history is very far from the view of history where all events and improvements are natural and immanent to this history. When Loewith intervened that it is merely the universal and necessary character seen in this idea of progress that does witness to Christian universal framework, from which standpoint it is formulated, Blumenberg acquiesced that the connection between the idea of progress and human self-assertion indeed might not be necessary and essential. Blumenberg used related notions to mark out modern transcendence: “empty transcendence,” always ready to be filled with ideological surrogates, and “projection of transcendence” that in his view was needed to bring the God of natural teleology with the

personal God of monotheist religions together. Nevertheless, Blumenberg wants to keep the notion of transcendence as a “basic term” for our world without codified norms and mandates to apply it critically to itself. This critical application could preserve transcendence in the Modern age from ideological misuse. What nevertheless remains unclear is what appropriate use as opposed to this misuse is. It seems that it is horizontal transcendence that comes to the fore: the place of transcendence has for him an anthropological meaning. With reference to Pascal’s notion of “immanent transcendence,” Blumenberg connects with this use the idea that man transcends himself and can never catch up with himself. Since then, the notion of “immanent transcendence” has been preferred to express the going beyond oneself within the immanent frame of reference for which the notion of horizontal transcendence was used as well (as an antipode to the “vertical transcendence” or “transcendent transcendence” referring to some kind of otherworldly principle or instance), i.e., legitimating anthropological versus theological use of the term. In the theory of nonlinear dynamics, it is the interaction of the system with its environment that is the necessary precondition of the possibility of its self-organizational transformations in chaotic astructural environments, and it is seen as internal transformation, as a product of the immanentization of the external (Nicolis and Prigogine 1977).

The main question was which transcendent pattern modernity refers to. Some theories about the origins of modernity proved to be more influential and were widely discussed on the continental scene. Karl Loewith stressed the Christian framework of modernity which at the beginning of Modern age was redefined in stoic terms (modernity as Neostoicism in the Christian aftermath). Hans Blumenberg believed to have discovered Gnostic traits in modernity, speaking of modernity as neo-Gnosticism understood as human self-assertion in a decisive reaction against Christianity dominant in the Middle Ages. The main idea was borrowed from Marcion as it was presented by Adolf von Harnack: the creation of the world by omnipotent God and

the salvation of man from this bad world cannot be the concern of the same divine person because it involves a dilemma. Christianity lays emphasis on the second outcome; Gnosticism prefers the first, and the Modern age repeats this Gnostic gesture (Harnack 1921; Blumenberg 1983). Some Jewish scholars maintained the idea of genuinely modern implications of Jewish monotheism or even negative theology. Thus, Aryeh Botwinick emphasized that it is the totally transcendent God who leaves room for this-worldly activities of man and even requires these activities, himself remaining withdrawn from this world. The modern world appears to be not a rejection of this transcendent order but an appropriate form of dealing with it. Tradition–modernity divide with regard to Judaism was called in doubt by Trigano who held that Judaism transcends this divide as well as that of religion and civility by arguing that the dialectics of transcendent and immanent aspects in Judaism itself not only come to full expression in Western societies in Modern age but existed already in Alexandrian Hellenism (Trigano 1995). All the three candidates for the revived sense of transcendence in Modern age, namely, Gnosticism, (Post-)Christian Stoicism, and Judaism offer very different conceptions of what the relationship between the transcendent and immanent is. While Loewith's theory promoted secularization (see ► [Secularization](#)) and was additionally charged with difficulties inherent in this ambiguous and subsequently widely applied term, Blumenberg's theory was faced with redefinitions in understanding of genuine gnosis and Gnosticism after the discovery of Gnostic writings in the midst of the twentieth century. However, there were commonalities as well. What Christian and Gnostic beliefs have in common is that man is related to or is created by transcendent God and belongs not only in the natural order. In Gnosticism, it is a foreign God, *deus otiosus* (see ► [Gnosticism](#)).

Science was the first phenomenon to be seen as a triumph of this immanent development of Modern age. Scholars in the nineteenth century would have liked to discover a more immanentistic religion as a kind of precursor to itself, as

well as invent the own genealogy with a help of primitive religiosity. Positivism in Comte discovered an immanent and mimetic power in fetishism ascribing supernatural or at least extraordinary powers to some objects or artifacts of human world. Even in the case of immanence, “specifically religious categorality” can be detected in, for example, radical atheistic materialists like De Sade's “Philosophy in boudoir,” 1795, or De LaMettrie's “Man–machine,” 1748, which pointed at “originary matter lying at the basis of whole reality” or to “the nature identical with it” and witnessed an immanentistic and sometimes “strong pantheistic religiosity.”

Marx's reading of the fetish character of the commodity inherits positivistic traits and interests in immanent religiosity, but the fetish in his view not just substantiates religion; it is rather a concept which makes it possible to interpret both religion and the secular religion of capital (as ideology, i.e., false consciousness). It was Hegel who denounced transcendence as separation from the world. The infinite (transcendent) is bounded by its counterpart (finite, immanent) and hence not truly infinite. Negating all finite determinations, this transcendence is indeterminate in its abstract universality. So, Hegel takes concrete determinations into godhead and makes world internal to God. Hegelian sophisticated immanentism has influenced many argumentative strategies up to this day. What singled out Marx's criticism of capitalism was its immanent character, in comparison to communitarians, utopians, and anarchists, whose critiques were based on standards external to capitalist economics. The most recent and widely discussed theory of transcendence and immanence in current time was offered by North American scholar Charles Taylor in the context of secularism debate. While Taylor discriminates public spaces or spheres of autonomous activities, in which we participate without any reference to transcendent reality, secularism manifests itself as an experience that conditions both belief and unbelief. Thus, the common understanding of secularization as rejection of belief in the transcendent (so-called subtraction theory) was challenged: we live today within the “immanent frame,” but this does not

necessarily exclude transcendence. Whereas horizontal transcendence does not require any ontologically transcendent being, the vertical one does. The latter does not imply any confrontation to (though no support from) science. Nevertheless, both kinds of transcendence are possible (Taylor 2007). Hegel-inspired critique reminded that transcendence is incompatible with the dynamic of spirituality: there is always only horizontal transcendence in the immanent development of *geist*. This position comes close to Nietzsche's approach. New immanentist impulses were initiated by the so-called Nietzschean diagnosis of the "death of God." The "death of God" theology (1961 by Gabriel Vahanian) arose in the United States and announced the death of God as a cultural fact, the fact that modern man functions intellectually and socially without God as a working hypothesis. Bonhoeffer laid emphasis on the idea that God that is not of this world posits a requisite "this-worldliness" of faith, which is not, however, absorbed by immanentism. This cultural fact, for Vahanian, implied a loss of the sense of transcendence and the substitution of a radically immanentist perspective in dealing with questions of human existence. Already late nineteenth- and early twentieth-century liberal theology laid stress on the immanence of God working in human experience and history, the possibility of Christians living out the ethics of Jesus, and evolutionary human progress while it downplayed divine transcendence and the power of sin. The liberal theology fostered an image of Christ as immanent within the culture and thus an active force for the kind of progressive social change that modernity itself seemed to promise. It came to be known as cultural Protestantism in Germany. Some attempts have been made to fuse scientific materialism with theology without giving up the sense of transcendence. On the Catholic side, an attempt was made by Jesuit pater and anthropologist Teilhard De Chardine who tried to integrate Marxism and evolutionary theory into theology, and even poetical "Hymns for Matter" was composed.

Transcendence in the sense of horizontal one can be exemplified in many different ways. The question might be about transcendence in

extreme sports (mystical and sublime features) which have a high degree of inherent danger and which are played out in nature where sportsmen have to master weather conditions and other obstacles of natural kind (water, snow, mountains). Post-modernity favors speaking of a "new experience" or transgression, a crossing of insurmountable limits (Blanchot) (by insurmountability, one can understand taboos existing in certain cultural traditions). Under that description come mystical experience, religious ecstasy (Bataille), death, and madness. All these phenomena are seen as opening new nonlinear possibilities of some further development. As far as horizontal transcendence is implied, there could be even talk about the transcending of transcendence (the reflexive use of the term). Caputo asks entirely in the spirit of horizontal transcendence: "do we need to transcend transcendence?" This reflexive use of the term can be duplicated in self-transcending. Tugendhat speaks of mystics as going beyond ego-centered experience and reaching in this way the famous peace of mind. The self-transcending accentuates activity on the part of the subject; it links it with passivity required for every serious experience of transcendence: self-transcending is transforming of suffering (passivity) into creativity (activity, spontaneity). Jaspers connects transcendence with immanence through emphasizing history: transcendence means the cipher, namely, hidden possibilities of existence making the empirical world a cipher for transcendence; it is in history (and cannot leave it) but points to transcendence through its historical embodiment here and now. He tries to synthesize both horizontal transcending and vertical transcendence, and individual therapeutic efforts and historical engagements, in order not to allow that therapy without explicit transcendent experience claims to become autonomic and make out religions of its own. According to Jaspers, the mere facing the vicissitudes of life is the way to transcendence. It happens as a leap, a spontaneous act that goes beyond rational procedure. The individual being located in a historical situation finds the transcendence through this situation, transcending it in both

directions – vertically (grounding his authentic being in transcendence itself) and horizontally (as engagements in the world, constructive acting that makes life worthwhile). The entering into relationships with transcendence requires the act deciphering: cipher brings transcendence to presence. For example, a particular event in history may become a cipher of transcendence for an individual.

Even the talk about possible worlds in philosophy and literature since the beginning of the Modern age (Bruno and others) can be regarded as a replacement of transcendence. In the popular culture of today, it is the turn to fantastic (or: myth, Joseph Campbell) that is a turn to the transcendent. The interactive immersion in fantasy, science fiction, and terror films can be explained by the deep “need of transcendence,” and even the “desire for transcendence” proves to be a fan’s need to transcend everyday mundane lives, examination of its limits, and the need to enter otherworldly environments for this purpose. The aesthetic experience (in comparison with pragmatical or epistemological experience) may be described as transcendent. The following assertion still holds true: it is the function of art to provide man with a transcendent ideal, toward which he can strive (Dostoevsky).

In recent decades, we can witness renewed attention to the question: how are religious ideals of transcendence materialized? In this connection, transcendence and loss or absence of presence were treated as parallel, so that the question was reformulated: how is loss (here: transcendence) presented? These questions involve more sophisticated ontologies of the material and immaterial by stressing the role of necessary character of materialization in what form so ever: “The agency of the absent . . . is never finite, but entangled in the dynamics of potential reverberation, reappearance, transformation and return” (Bille, Hastrup, Sorensen) (Bille et al. 2010).

There have been lots of secular religions in the past 300 years, most of them seeking basis in sciences. In “secular or implicit Theology of economics” (Samuelson) that legitimates free-market capitalism, where the good is that which is efficient and evil that which is inefficient,

it was actually economics that – according to Robert Nelson – since the beginning of Modern age has been the source of the most influential religions in public life. As the Judeo-Christian religion had lost much of its earlier authority in public life, posing a large transaction cost problem for the functioning of economic institutions, much of the authority was transferred to science. As dispenser of valid truth claims (see ► [Truth](#)), science became the greatest religious authority in modern society. The success of economics in its religious function was independent of the degree of validity in the specific truth claims produced by economics as science. Economics is to be held not just a positive science but a normative one and might be called secular theology (Nelson 2001). In matters of social action, the role of authority was taken over by social sciences which became the religion of Modern age and assumed transcendent significance in promising the arrival of a future heaven on earth. Since the mid-nineteenth century, people sought a secular salvation through abolishing economic scarcity and arriving at a state of complete material abundance on earth. Economists had to solve transaction cost and collective action problems arising from the loss of transcendent goals. The modern religions of economic progress fell short of expectations, and modern fundamentalisms with their own sense of transcendence were began emerging as a consequence of the turning away from the former in form of communism, socialism, or welfare capitalism. While the transcendent purpose of progress made all involved in it ready to carry any burdens and put up with any difficulties on the way to this aim, the purposes, emancipated from transcendent goals, made progress immanent, involving transaction costs which previous religion was better able to reduce because it fostered trust lacking now. Environmentalism or environmental theology (broadly speaking the belief in inherent right of nature or its intrinsic worth) which initially came to the fore in German Lutheran, American Anglican, and Swiss reformed circles as ecology science is according to Nelson a religion next to economics. Both libertarianism and environmentalism have the

same roots. Evolutionary laws of nature presume that human progress is achieved by competitive struggle in society, and so, references to nature make market economics almost theologically legitimate. Natural theology underlying economics as an implicit theology presumes some redemptive quality in nature whose purpose is human welfare and that always acts wisely making creative use of human faults, so to say, good out of evil. The good in environmentalism is the natural; the evil is the unnatural. This view relies on teleological notions but sets them in a Christian framework thus producing some irresolvable dilemmas. The main objection to that is as follows: “God is the creator not the creation,” and accordingly, not nature/creature has to be revered but the Creator.

The “consumer theory” within the neoclassic theory turns out to be a kind of “religious anthropology.” This theory is characterized by an asocial view on human being who is obliged to pursue individual happiness and by lack of a historical time dimension (the consumer prefers “now”; there is no “tomorrow” for him) and consequentialism in achieving an immediate satisfaction and is seen by Judeo-Christian tradition where every decision is situated in the history from creation to fulfillment at the end of time, as a deep failure (Nixon 2007). This secular metanarrative of human satisfaction is nevertheless normative and can be countered by traditional religious anthropologies. Many of the key metaphors and models of divine–human interaction presented in Judeo-Christian tradition are economic – such as redemption, reconciliation, and stewardship (Oslington). Therefore, reconnection of economics with theology, part of which was used before the divide in the mid-nineteenth century, is seen today as possible and welcome. As appropriate for these reconnections are mentioned the Smithian model (natural theology tradition) and the Aristotelian-Thomistic model on the Christian part. The main ideas substantiating this reconnection remain the Judeo-Christian doctrine of creation, prescribing creativity continuous with God’s creative purposes, and the doctrine of the fall that cautions against human fallibility.

In modern philosophy due to its solipsistic and dualistic inclinations, it was the object of ordinary knowledge that was depicted as transcendent, and its accessibility constitutes the main problem of modern epistemology. The science captures “transcendence” understood as “structure” as it does in the case of “molecular transcendence” (Baudrillard).

The meaning of transcendence developed by Husserl exerted a heavy influence on philosophical and religious theories. The concept of “phenomenological immanence” can be interpreted as having a normative structure, and “noema” is a mental entity which depends on how the world is. The noematic and intentional moments transcend the phenomenologically given (material), immanent, to be more exact. Phenomenological reduction “is not the exclusion of the really transcendent but of the transcendent as such as a supposed existence, i.e., the exclusion of whatever is not in the authentic sense evidently given, absolutely given in a pure intuition” (Husserl 1950). “*Absolutely given* and *really immanent* are no longer obviously and unquestionably one and the same.” Husserl undertakes to double-determine the concepts of “transcendence” and “immanence”: phenomenological immanence includes intentional immanence, which is a real transcendence. Transcendent here is something fundamentally other, non-real, and not really immanent to consciousness. There is an “absolute sphere of materials and of noetic forms in phenomenological reduction to whose determinately articulated texture belongs with immanent essential necessity this marvelous conscious grasp of what is given as determinate or determinable” (Husserl 1950). There lies the very possibility of an objectively valid cognition of the transcendent. Transcendence is constituted in the immanence of subjectivity through the phenomenological reduction. The absolute being, defined with the help of Descartes formulation of substance, contains in itself all mundane transcendences. Merleau-Ponty seeks for a primordial realm underlying the traditional polarizations of transcendence and immanence. The lived body fits in this search, and it allows seeing flesh as an elemental reality characterized by reversibility, based on the image

of a fold and of the body as the place of this fold by which the sensible reveals itself. In Sartre, all objects of consciousness (mental images) transcend consciousness; therefore, consciousness cannot reflectively grasp itself as a transcendent object. Perceptual objects perceived by consciousness are transcendent and so are mental images.

Spiritual transcendence refers to a perceived experience of the sacred that affects one's self-perception, feelings, goals, and ability to transcend one's difficulties and belongs to individual phenomena. To counter the difficulties in conceptualization and measurement of religiousness, the Spiritual Transcendence Index was developed which was an eight-item measure of this construct in which "cognitive aspects of spiritual transcendence refer especially to the influence of spirituality on one's sense of meaning and purpose, and affective components center on feelings of fulfillment and spiritual communion" (Seidlitz et al. 2002).

The transcendence–immanence relationship remains a crucial issue in monotheism. There is an infinite distance between God and man that cannot be diminished or bridged over. Transcendence prevents God from being represented through images or being characterized or described. Transcendent God can only be characterized with a name; therefore, theories of reference appropriate to radical transcendence single out the reference through the name. The inherent problem is that the more transcendent is God (for example, in Platonism), the more there is (actual a) need for mobile instance that would guarantee communication between God and man. Traditional gods become in such cases divine mediators or intermediate beings or even demons. That means that the increasing role of intermediate beings can be seen as a correlate for reinforced monotheistic, transcendent tendencies in order to find some balance in contact with the transcendent being and appropriate immanent counterparts, for it and should not be necessarily seen as a triumph of immanent tendencies going on along their own paths. A most disputable question is the one concerning mysticism with regard to immanence–transcendence distinction.

The main problem is that transcendence in radical monotheism implies theoretical inaccessibility to – or at least real dependence of creature/man on – the Absolute that is depicted in voluntaristic terms (omnipotence, omniscience). Is there not an inherent danger of immanence that is involved in mysticism of even monotheistic religions? Sometimes, it is claimed that religious ethics is much more suitable for grasping transcendence than religious mysticisms might be. Mystical experience is properly religious, however, when it preserves the transcendence of the Absolute by maintaining a tension between it and the self to which it is united.

Transcendental Sense of Physics

Alexei Nesteruk
University of Portsmouth, Portsmouth,
Hampshire, UK

Physics is seen not only as a compendium of facts and theories about the universe as it is in itself, but as a structural path of humanity in its comprehension of the universe, the path which is historically concrete and includes the conditions of observability and mathematical expressibility of reality. Thus physics is a historically contingent human enterprise which represent nature as manifestation rather than the manifest.

Transcranial Magnetic Stimulation

Ulf Ziemann
Department of Neurology and Stroke, Hertie
Institute for Clinical Brain Research, Eberhard-
Karls-University, Tübingen, Germany

Related Terms

[Human brain](#); [TMS](#)

Description

Transcranial magnetic stimulation (TMS) refers to painless and noninvasive stimulation of the (human) brain through the intact skull utilizing the fundamental principles of electromagnetic induction (Faraday's law). Thus, an electrical current in the stimulating coil generated by discharging a capacitor induces a changing magnetic field around the coil that in turn induces an electrical current in nearby conductors, such as brain tissue. TMS in its contemporary form was inaugurated by Anthony Barker (born 1950) at the University of Sheffield in 1985 (Barker et al. 1985). The idea to stimulate the brain is much older and goes back to experiments by the German anatomist and physiologist Gustav Theodor Fritsch (1838–1927) and the German neurologist Eduard Hitzig (1839–1907) who proved by galvanic electrical stimulation of the exposed motor cortex of dogs that the brain is electrically excitable. Based on high-power electronics, TMS developed into a rapidly growing field since 1985. The major applications are noninvasive assessment of the function of corticospinal tract as a diagnostic tool in ► [clinical neurophysiology](#) and the assessment of brain function by inducing a transient virtual lesion as a research tool in ► [cognitive neuroscience](#), *neuropsychology*, or *neurophilosophy*. In addition, repetitive TMS protocols provide means for treatment of patients with *neurological disorders* or *psychiatric disorders* through induction of long-term changes in excitability and/or connectivity of the stimulated brain regions (therapeutic tool in *clinical neurology* and *psychiatry*).

Self-identification

Science

TMS is a technique (rather than a discipline). It has self-identified as a *tool in neuroscience* (a subdiscipline of the *natural sciences*) from its early days. It was primarily invented to achieve noninvasive access to the function of the corticospinal tract (*central motor system*) in

humans. In this case, TMS quickly gained clinical utility as a *diagnostic tool* in neurological disorders with affection of the corticospinal tract such as amyotrophic lateral sclerosis, multiple sclerosis, stroke, or myelopathy. Typical pathological findings are muscle responses (motor evoked potentials) that are delayed (prolonged central motor conduction time) and/or reduced in amplitude. More recent technical developments (e.g., paired-pulse protocols) allow measurement of motor cortical excitability, in particular abnormal excitability in neurological disorders such as epilepsy, or under the influence of central nervous system active drugs (pharmaco-TMS). Self-identification as *tool in cognitive neuroscience* came from the demonstration that TMS (or repetitive TMS) can transiently disrupt physiological neuronal brain activity which is considered fundamental for any cognitive or behavioral process. TMS can lead to disruption of the particular process for which normal function of the stimulated area is necessary. Finally, TMS currently evolves as a noninvasive therapeutic tool in neurological and psychiatric disorders with the intention to normalize altered brain excitability.

Characteristics

TMS is distinctive because it stimulates the brain in a painless and noninvasive manner. This contrasts with other methods of brain stimulation. *Transcranial electrical stimulation* was developed in 1980 by the British neurophysiologist Patrick A. Merton (1920–2000) but was never broadly used because it is painful due to the high voltage needed to pass the electrical current through the intact skull to stimulate the brain. *Direct cortical electrical stimulation* is an invasive technique performed (often in concurrence with electrocorticography) for functional mapping of the cortex and identification of critical (“eloquent”) cortical structures during brain surgery. Another invasive technique uses chronic electrodes implanted into the brain. They may record

electrical impulses in the brain or they may stimulate brain tissue (e.g., through intracortical microelectrodes delivering electrical impulses from an external source). One currently important application is ► [deep brain stimulation](#) (DBS). This technique is best established for treatment of *movement disorders* such as Parkinson’s disease, essential tremor, and dystonia. The *Food and Drug Association* (FDA) has approved DBS for all of these indications as *evidence-based therapy*. Emergent, not yet approved indications of DBS include epilepsy, chronic pain, and obsessive-compulsive disorder. Another application of chronically implanted intracortical microelectrodes is to record neuronal brain activity. The recordings can be used to navigate *brain computer interfaces* (BCI) or *neuroprostheses*. These devices can partly substitute neuronal function that is no longer available to the patient due to, e.g., complete paralysis in advanced amyotrophic lateral sclerosis to allow communication with the environment (e.g., through BCI spelling devices).

TMS is also distinct from other methods of ► [clinical neurophysiology](#), such as *electroencephalography* (EEG), ► [magnetoencephalography](#) (MEG), or functional magnetic resonance imaging (fMRI), which record noninvasively neuronal activity of the brain (EEG, MEG) or directly related changes in cerebral blood flow (fMRI) but cannot be used for stimulation of the brain. Recent technical developments combine TMS with EEG or fMRI to measure directly the effects of TMS on brain activity.

Relevance to Science and Religion

TMS is used as a tool in cognitive neuroscience. TMS-induced perturbation of physiological brain activity allows assignment of cognitive function to the stimulated brain area or network if cognitive performance is altered by the stimulation. This bridges the gap between human brain *physiology* and cognition, such as emotional control of behavior, decision making, communication, attention, or self-consciousness.

Sources of Authority

TMS is rooted in a long tradition of attempts to stimulate the cortex by electrical current. In England, the physiologist and Nobel laureate Sir Charles Scott Sherrington (1857–1952) and in Germany the neurologists Oskar Vogt (1870–1959) and his wife Cécile Vogt (1875–1962) were the first in early twentieth century to prove the *somatotopic* organization of body representations in monkey motor cortex. These investigations were followed up in the 1930s by the German neurologist and neurosurgeon Otfried Foerster (1873–1941) in Breslau, and the Canadian neurosurgeon Wilder Penfield (1891–1976) in Montréal, who used *direct cortical electrical stimulation* in conscious patients to map the functions of human cortex. Until today, direct cortical electrical stimulation is the gold standard to identify functionally critical cortex prior to brain surgery. Along this vein, there was a long standing need for development of noninvasive techniques for stimulation of the human brain. In the 1980s, transcranial electrical stimulation (TES) and TMS were successfully invented to investigate the functional integrity of the human corticospinal tract through the intact skull in neurological patients (see above). For this purpose, TMS is nowadays a routine technique in ► [clinical neurophysiology](#). Authority to the clinical diagnostic utility of TMS in several neurological disorders (amyotrophic lateral sclerosis, multiple sclerosis, and myelopathy) has been given by *consensus guidelines* issued by the *International Federation of Clinical Neurophysiology* (ICNF) for diagnostic use, clinical diagnostic utility, and safety of TMS. But TMS has diffused far beyond the borders of clinical neurophysiology into cognitive, perceptual, behavioral, and therapeutic investigation. Several authoritative recent textbooks witness this broadened scope that attracts a highly diverse group of users clinical, cognitive, and basic neuroscience (Siebner and Ziemann 2007; Wassermann et al. 2008). Currently, more than 1,000 scientific papers on TMS are being published every year worldwide in international peer-reviewed journals. International scientific conferences on TMS take place at a regular scheme.

Ethical Principles

As for every medical subdiscipline, TMS applications are guided by the oath and law of the ancient Greek physician *Hippocrates* (born 460 B.C.) who is considered the so-called father of medicine. This “Hippocratic Oath” has been supplemented by the rules of the *Declaration of Helsinki* of 1971.

Key Values

Key values of TMS are (1) quantitative diagnostic investigation of corticospinal tract function that supplements clinical neurological examination and neuroradiological investigation; (2) proof of functional significance of the stimulated brain area or network making TMS an important tool of cognitive and behavioral neuroscience. In this respect, TMS is complementary to traditional research rooted in deriving knowledge from abnormal or absent function after brain lesions caused by, e.g., trauma, stroke, or brain tumors, and complementary to modern neuroimaging techniques such as functional magnetic resonance imaging and; (3) therapeutic efficacy in psychiatric and neurological disorders.

Conceptualization

Nature/World

Nature is conceptualized as the *biological* and *biochemical* foundation of life on our globe. Nature entertains all dynamic processes in the observable environment. The world comprises the material and the interspersed space of the universe.

Human Being

The human being is considered as a biological *being* equipped with a highly developed complex brain, which enables unique functions including speech, abstract thinking, creativity, and the development of ethical categories such as morality, science, and art. Thus, humans are

considered to be distinctive from the rest of the animal world by virtue of the unique capacities of the human brain.

Life and Death

Life is conceptualized as the presence of physical functions in biological systems ranging from bacteria over plants and animals to humans. In the human body it includes functioning of the different organs, including the *nervous system*. Death is considered the cessation of such physical functions. A special case, which has raised ethical challenges for Medicine, is that of so-called brain death, which is observed in intensive care medicine. Here, non-brain bodily functions are maintained, but there is no evident brain activity.

Reality

Reality is considered the physical world around us that humans can observe with their senses.

Knowledge

Knowledge is understood to have an *objective* dimension, such that it is the *wisdom* that can be transferred in a verbal form from one person to the next, or has been written down in books or libraries. However, knowledge is also understood to have a *subjective* dimension, which is taken to be the amount of information a person can retrieve from *memory* voluntarily, or by being *cued*.

Truth

Truth is conceptualized as the supreme reality underlying facts and rules. Accordingly, truth is assumed to be absolute or universal which humans can grasp only partially.

Perception

Perception is the *conscious sensation* of the forces and influences the external physical world exerts on living beings. Diseases of the human brain may disrupt or impair perception.

Time

Time is the fundamental category of ongoing change in the world. Humans can measure time *objectively* and perceive it owing to the changes

observed in the surrounding environment. Human perception of time can be affected by the focus of *attention* or impaired by diseases of the brain.

Consciousness

Consciousness is the responsiveness of subjects to any physical stimulus in the outside world. It can be graded in different levels of *alertness* ranging from drowsiness to full *alertness*, which comprises crystal clear orientation concerning location, time, situation, personal biography, and full mental capability. Diseases can impair consciousness globally, or in differentiated fashions.

Rationality/Reason

Rationality is a foundation of accountable and *responsible* human behavior and of understanding reason as ultimate authority. It is impaired in mental diseases such as *dementia* or neuropsychological *disorders*.

Mystery

Mystery is considered that what is as yet unknown, and, thus, grants that contemporary knowledge may not have elucidated the entire physiology of human kind. In this view, mystery is understood as potentially explainable after accumulation of adequate scientific knowledge.

Relevant Themes

An emerging theme as regards “Science and Religion” is to use TMS (in combination with other techniques such as functional brain imaging) as a tool of behavioral neuroscience to understand the neurophysiological foundations of religious thoughts and views. This theme is based on the concept of ► [materialism](#), a philosophical theory of the mind-body problem, i.e., mental phenomena (such as *religious thought*) are neuronal phenomena. Pathophysiological aberrations, such as religious delusions in psychiatric disorders may also be tackled by modern techniques of systems neuroscience, including TMS.

Description

Blood has always represented an important element in human culture because its appearance has, even to the present day, been associated with significant emotional reaction system as well as its potential therapeutic usefulness. Both in ancient and more recent times, blood has had

many interesting and not widely appreciated connotations. For example, from a therapeutic point of view, bloodletting (in modern medicine usually referred to as phlebotomy) was a popular medical practice used in antiquity and even in the twentieth century, to treat certain medical conditions. Bloodletting over the years (particularly during the last millennium) has involved the withdrawal of considerable quantities of blood from a patient often in the mistaken belief that it would cure the patient of their ailments. While it is conceivable that, in the absence of other treatments for hypertension, bloodletting may very well have had a short-term beneficial effect in patients with this condition, particularly in reducing blood pressure by the temporary reduction of the blood volume. Of necessity, this effect would have been short-lived as the body's innate homeostatic mechanisms would have soon replaced the reduced blood volume in a matter of only 1 or 2 days.

Human beings appear to have always been aware of blood and the implications of its appearance. Hemorrhage is commonplace and often results in a death. Thus, there is evidence of an awareness of the importance of blood even by prehistoric man, who left drawings of blood emanating from an injury caused by an enemy's arrow. Early in human history, blood was celebrated in religious rituals as an important life force. The Bible in Leviticus (17:11) indicates that "blood is the source of life." Not surprisingly, therefore, was blood often seen as a potential therapeutic agent. Egyptians bathed in it to cure leprosy. Hunters drank the blood of fierce animals to pass such attributes to themselves. Warriors drank the blood of fallen enemies in the belief that their opponents strength, courage, or even wisdom would be passed onto themselves. Romans drank the blood of fallen gladiators as a cure for epilepsy. At hangings in England, during the middle ages, the crowds were so numerous in the quest of blood from a newly executed criminal, to be used as a curative, that a physician's "prescription" became a requirement to attend such events!

It is interesting to note that of the four ancient humors, *blood* alone remained an entity with both

magical and therapeutic powers. There are two reasons why blood has always enjoyed special status. First, it is clearly visible when shed, being the only organ with which most individuals can readily identify. Every injured person knows that bleeding represents that injury, whose severity can easily be gauged by the volume of blood that can be observed. Second, blood has always been associated with life itself, and in many languages, the term “blood” is synonymous with both life and good health. In the Bible, “to take someone’s blood” means to take someone’s life. Thus from a therapeutic point of view, if blood represents life, it does not take great intuition to be able to logically assume that someone who is dying might be successfully treated with blood or alternatively by the removal of their “bad blood.” It is important also to understand that until the twentieth century, physicians had precious little to offer their patients, except herbs, baths, bloodletting, leeching, and cupping. Thus the “balancing of the humors” through bloodletting was a major form of therapy, well into the eighteenth century.

Apropos of the foregoing, it is of interest to relate exuberant bloodletting to the death of the first president of the United States, George Washington, who died in December 1799. While no one is quite sure of what he actually succumbed, it appears that at age 67, he developed a form of acute hoarseness and severe sore throat (probably due to a bacterial form of acute epiglottitis). As he was not responding to the conventional forms of therapy available at the time, he was subjected to three episodes of bloodletting over a 12-h period. This resulted in him having at least 80 oz (over 2½ L) of blood removed, which represented the removal of approximately one-third of his blood volume. He died the next day, before a fourth bloodletting was to have taken place! Historians have suggested that the bloodletting probably contributed significantly to his demise (Morens 1999).

Blood was thought to have special magical powers and, as a result, was widely used as a “curative” agent. Both human and animal blood have thus been administered to patients, as a salve to be applied topically, as a draft either

to be imbibed orally, or as a therapeutic agent to be infused subcutaneously, intramuscularly, intravenously, or by surgical manipulation. The first intravenous use of human blood was in 1818, but transfusion episodes to humans, using animal blood, had been done since 1667. In the two centuries since the first transfusion involving human blood, a variety of techniques and devices have been used to accomplish the intravenous administration of blood. However, it is only during the twentieth century that blood and its derivative products been transfused successfully to replace what is deficient in relevant recipients.

Curiously, there is widely cited a legend that suggests that blood was first transfused to a human over 500 years ago and that this blood transfusion was given to a dying Pope – Pope Innocent VIII, in 1492. This legend recounts that the Pope’s Jewish physician of the time tried to revitalize him by giving him blood from three 10-year-old boys, from whom the physician took a sufficient quantity to cause their death. The evidence that this particular legend is reliable is weak. This legend has recently been traced back to only the early nineteenth century (Gottlieb 1991). It is very likely therefore that this legend represents an anti-Semitic fabrication relating in kind to the various blood libels that had often resulted in the accusation of Jews carrying out ritualistic child murders to serve the needs of the customs for their Passover holiday. Such fabrications often lead to pogroms resulting in the deaths of many Jews.

Definition of Transfusion Medicine

The author of this present entry has previously (1990) published a definition of transfusion medicine as “That multidisciplinary branch of medicine that focuses on all the available medical, scientific and technical information applicable to this specialty for the benefit of patients receiving blood products or related materials produced by biotechnology. Those engaged in the practice of Transfusion Medicine have the responsibility of integrating the various scientific concepts, techniques, and other elements of

relevant knowledge from contributing disciplines such as blood banking, immunohematology, hematology, infectious diseases, immunology, transplantation biology, genetics, protein chemistry, molecular and cell biology, clinical medicine, laboratory sciences, epidemiology, microbiology, and virology. Issues relating to the recruitment of donors and the collection of whole blood and blood components, such as the psychology of the motivation of donors, are also germane, as are legal and ethical questions associated with the collection and the clinical use of blood products. Those engaged in Transfusion Medicine should also be involved in education and research relevant to the specialty (Blajchman 1990)."

Self-identification

Science

The development of transfusion medicine as a distinct subdiscipline began with the dawn of the twentieth century. In 1905, Karl Landsteiner (1868–1943) published a short paper in which he identified, for the first time, differences in the human blood cells (RBCs) in different individuals. With the elucidation of the major RBC blood groups into A, B, and C (now called group O), Landsteiner's seminal work opened the door to the possibility of safely providing immunologically compatible blood transfusions to patients who were either bleeding or anemic for other reasons. This major advance allowed blood to be transfused to individuals with relatively few adverse immunological outcomes. Landsteiner's work opened the door to the recognition of hundreds of other RBC blood group antigens as well as to the identification of antigens on the other circulating blood cells including the various types of white blood cells and platelets. Blood transfusions were certainly used for the treatment of the injured during the First World War, but it was not until the Second World War when it became widely used standard practice. In the 60 years since, improved methods for the preparation and storage of blood products have been devised. Thus at the present time, RBCs can be stored, in the liquid state, for up to

6 weeks! Techniques for the preparation and storage of most of the other blood components have also been developed, including platelets and the various plasma components which can be extracted from the plasma obtained from whole blood donations. Thus, as outlined in the definition provided above, transfusion medicine has defined itself as a scientific endeavor which has effectively enhanced knowledge to facilitate the provision of effective and safe blood products to be given to patients relevant who require them.

Religion

The basis of this subdiscipline is primarily scientific, which requires ongoing basic and applied research and which requires evidence-based data to show that the various blood products are clinically efficacious when transfused to patients.

Nonetheless, because of historical practices related to the use of blood, there still are many religious beliefs associated with blood. In this regard, Goethe in *Faust* made the comment that "Blood is very special liquid (Blut ist ein ganz besonderer Saft)." In this context, it should be noted that there is a Christian religious group known as the Jehovah's Witnesses, who believe that they should refuse blood transfusions as a therapeutic option, even if they can save a human life. This belief is based on various Biblical passages (Old and New Testament) forbidding the *eating* of blood. While it is clear that the transfusion of blood does not represent the "eating" of blood, Jehovah's Witness patients requiring a blood transfusion can represent a very significant problem for their physicians. Apropos of the preceding, it is important to note that the Jehovah's Witnesses have recently moderated their stance about the use of blood products and at the present, time allow adherents the option of deciding that some interventions might be acceptable to each person individually. Thus, the Jehovah's Witnesses have indicated that the use of some blood products and practices (i.e., the use of blood fractions or stem cells for transplantation) are to be left to an individual's conscientious decision (Bodnaruk et al. 2004). The Jehovah's Witnesses thus acknowledge that

some past interdictions in the therapeutic use of blood may have been based on overinterpretation of the biblical prohibition to *eat* blood.

Characteristics

Transfusion medicine is a subdiscipline of medicine that is quite distinctive from most other subspecialties of medicine/surgery. Transfusion medicine is a subdiscipline that interacts with most of the other disciplines of medicine, in that it provides the scientific rationale as well as the therapeutic materials that might often be needed by patients who are deficient in certain blood components or proteins derived from whole blood or plasma. In this regard, practitioners of transfusion medicine can effectively interact with those of other disciplines, including those in surgery, internal medicine, gastroenterology, obstetrics, gynecology, intensive care medicine, etc., to provide the blood products needed by their patients (Duffin 1999).

Relevance to Science and Religion

It is clear from the above that transfusion medicine currently is a scholarly area of scientific endeavor. This has become particularly true since the AIDS epidemic of the early to mid-1980s, when it was shown clearly that the AIDS virus (HIV1/2) can be transmitted to recipients by transfusion. This tragic realization highlighted the importance of transfusion-transmitted infections. Many such HIV1/2 transfusion-transmissions have been documented, and as a result, a considerable research effort has since been mounted in an attempt to reduce the risk of the transfusion transmission of infections of all types (viruses, bacteria, protozoa and prions) (Blajchman and Vamvakas 2006). While this endeavor has been quite successful, it has become evident recently that blood product transfusions can also result in transfusion-associated deaths due to causes other than those due to transfusion-transmitted infections. For example, one of the most common transfusion-associated morbidity and mortality risk is a clinical entity known as

transfusion-related acute lung injury (TRALI). Other noninfectious adverse events related to transfusions include transfusion-associated circulating overload (TACO), graft-versus-host disease (GvHD), and hemolytic transfusion reactions often due to ABO incompatibility. The latter are usually due to the administration of the wrong product, usually due to an error, giving the recipient the wrong type of blood (i.e., A blood to an O recipient). At this point in time, the noninfectious risks of blood transfusion account for more than 85 % of the transfusion-associated mortalities reported to regulatory authorities. Despite the attention they continue to receive, transfusion-associated infections account for less than 15 % of the deaths caused by or attributed to blood transfusions.

It is important to note at this time that the blood donor who provides the raw materials for the manufacture of the various blood products that are transfused to patients requires the interdisciplinary interaction between those involved in transfusion medicine and relevant disciplines which can ascertain the best ways of encouraging blood donation as well as to understand the barriers to volunteer blood donations. However, compared to the many scientific endeavors associated with Transfusion Medicine, these nonscientific endeavors are still somewhat underdeveloped but nonetheless very much related to the scholarly area known as “Science and Religion.”

Sources of Authority

The authoritative sources for transfusion medicine are generally the scientifically based physicians and scientists who clearly are members of academic institutions worldwide. As indicated above, the father of modern Transfusion Medicine, Karl Landsteiner, was a physician-scientist. Landsteiner was awarded the Nobel Prize in 1930 for his seminal work identifying the ABO blood group system. This discovery led to safer blood transfusions and eventually to the scientific endeavor now known as Transfusion Medicine. During the last two decades of the twentieth century, many

academic chairs in transfusion medicine have been established worldwide in many university-affiliated faculties of medicine. These positions are often held by distinguished and authoritative transfusion medicine scholars. In addition, many textbooks on transfusion medicine have been published, as have learned journals which publish peer-reviewed authoritative articles by transfusion medicine physicians and scientists. These include the journals *Transfusion*, *Transfusion Medicine Reviews*, ► [Transfusion Medicine](#), and *Vox Sanguinis* to name but a few. Based on these books and journals, as well as the widespread use of the Internet for scientific communication, there is a rapidly expanding scientific knowledge base related to transfusion medicine and Transfusion Science which have established an authoritative evidence-based transfusion use of blood products for patients (Blajchman and Klein 1997).

Ethical Principles

Transfusion Medicine, as is the case currently for every medical discipline, is guided by clearly enunciated ethical principles, based primarily on the Hippocratic Oath. Hippocrates, a Greek physician who formulated the Hippocratic Oath is generally considered the Father of Medicine. More recently, the Hippocratic Oath has been supplemented by various other relevant statements of ethical principles, primarily that of the Declaration of Helsinki which was initially enunciated in 1971 and updated regularly since. Thus, transfusion medicine practice and related research activities are carefully monitored to ensure ethical practice by its practitioners.

Key Values

The key value of transfusion medicine is to provide the safest possible transfusion products, derived from that special fluid “blood,” to give to patients who need them to correct their specific deficiencies. Because transfusion medicine practice occurs worldwide, tens of millions of blood products are transfused annually. Thus,

the most important value for this subdiscipline is to provide safe and effective blood products to patients!

Conceptualization

Nature/World/Human Being

Since transfusion medicine deals with only humans, nature is conceptualized primarily on the scientific knowledge as to how the human body functions in all of its biologic complexity and diversity.

Life and Death

Transfusion medicine plays an important role in the life and death of the human beings both of which constitute times when its practitioners play an important role!

Reality

The reality for practitioners of transfusion medicine is that while we play an important role in the maintenance of human life, death is an outcome over which we often have little control. This is usually a time that religion also plays an important role for many individuals.

Knowledge

Transfusion medicine views knowledge (particularly scientific knowledge) as ever expanding and readily transferable among those involved in this subdiscipline.

Truth

Truth in transfusion medicine is ever changing, based on current scientific understanding and the evolution of changing scientific paradigms.

Perception

Perception in transfusion medicine is also continually in a state of flux, depending on contemporary scientific knowledge and thinking.

Time

Time is an ongoing change in our state of being, which we cannot control, except by keeping up to date in the knowledge base of our subdiscipline.

Mystery

As outlined above in detail, history has often and to this day seen blood a magical and mysterious fluid or substance. The advent of scientific methodology in this subdiscipline since 1900 has nonetheless provided for an improved understanding and appreciation of the mysteries of blood – that “special” fluid that often sustains life.

Transpersonal Studies

Glenn Hartelius¹, Harris Friedman² and Adrian Andreescu³

¹Sofia University, Palo Alto, USA

²University of Florida, Gainesville, USA

³Independent Researcher, Pucioasa, Dambovită, Romania

Description

Transpersonal studies are a group of interdisciplinary orientations to scholarship concerned with the examination of various topics from perspectives that stem from science and the humanities. The scientific areas (e.g., transpersonal physics) challenge the reductionistic and mechanistic assumptions typically associated with science, while the humanities areas approach their topics from a similarly broadened perspective (e.g., transpersonal art history) (Friedman 2002). The transpersonal orientations evolved out of initial work in transpersonal psychology, which originated in the 1960s, as the need for transpersonal approaches to various disciplines in addition to psychology became apparent. By the 1990s related disciplines had been birthed, such as transpersonal anthropology, sociology and social work, medicine, education, ecology, art, literature, acting, law, and business (Boucoulalas 1999). While several of these remain in nascent form, others such as transpersonal anthropology are sufficiently developed to be recognized as independent disciplines in their own right (Laughlin 1989). In addition there are closely related fields not carrying the transpersonal name, such as ecopsychology and somatics, which can be seen as transpersonal, at least in part. A transpersonal approach can also be applied within fields such as cultural studies, ecology, neuroscience, pharmacology, philosophy, politics, psychiatry, and religious studies (Daniels 2005). Transpersonal psychology shares some values with feminism, as well as with the field of cultural studies (Brooks 2010). The transpersonal studies perspective is thus one that can be widely applied.

The transpersonal movement began in the United States through experimentation with mystical practices and psychedelic substances that induced non-ordinary states of consciousness (Hartelius and Friedman 2010). In these altered states the nature of reality seems to be not just mere bits of rule-following matter, but an interconnected, self-organizing, and evolving system that may be informed by wisdom and compassion, as well as driven by selfishness and impersonal forces (Grof 1983). Human beings were seen from this vantage as capable of cultivating personal development beyond the conventional socialized ego to what was called the transpersonal (Maslow 1969). This process, though explained in non-religious terms such as personal growth and self-actualization, is closely related to the spiritual development underlying various traditions, such as Buddhism, Advaita Vedanta Hinduism, and mystical branches of various religions and indigenous spiritual paths. Transpersonal psychology, founded in the late 1960s, was the first discipline to form within this movement, and its early leaders came largely from the humanistic psychology movement, including Abraham Maslow, Anthony Sutich, Stanislav Grof, James Fadiman, Miles Vich, and Sonya Margulies (Grof 2008). These first transpersonal psychologists felt that humanistic psychology held an overly restrictive view of human nature, and proposed a psychology that went beyond human nature to connect more broadly with the cosmos, including spiritual realizations (Hartelius and Friedman 2010; Grof 1983). There are now a number of academic degree and certificate programs offered in transpersonal studies (e.g., Atlantic University, California Institute of Integral Studies, Saybrook University, Sofia University), a school named after the orientation (Manchester Academy for Transpersonal Studies), and a journal targeted to its topic areas (International Journal of Transpersonal Studies).

Self-identification

Science

Transpersonal studies spans both scientific disciplines such as transpersonal psychology,

anthropology, and sociology, as well as non-scientific areas of study such as transpersonal art, literature, and religious studies (Friedman 2002; Boucouvalas 1999). In its scientific disciplines, transpersonal studies embraces the use of systematic scientific methods for gathering evidence, and uses this evidence to support or refute its theories (Friedman 2002). It is committed to a broad yet skeptical empiricism that considers phenomena within multiple epistemological frames. As such, it rejects both any romanticism that interprets evidence through an idealizing frame and scientism that maintains an allegiance to simple physicalist philosophical assumptions as if these were proven scientific fact. In this sense it maintains a commitment to examining the processes of knowing even as it employs these to gather knowledge.

Transpersonalism can be critiqued for its relatively modest output of empirical work, in line with similar criticisms of the closely related field of humanistic psychology. Yet the theoretical and philosophical emphases of the orientation is a reflection of the fact that transpersonal studies is engaged at the foundation of the scientific process, struggling with how Western notions of reality may, in the course of useful knowledge-gathering, also distort certain kinds of evidence (Grof 1983; Maslow 1969). This potential for distortion relates particularly to aspects of human life that do not fit comfortably within a rational frame, such as spiritual and non-ordinary experiences. The focus on these issues comes from an interest in the accuracy of knowledge, but it is also concerned about how the assumptions of a materialist philosophy reduce human experience through mechanistic interpretations of human nature. In this sense, transpersonal studies align with critical theory as a way of thinking that seeks to liberate human beings from oppressive systems (cf. Brooks 2010).

Religion

Transpersonal scholars often give serious consideration to the reality-assumptions of spiritual and mystical traditions, but typically in a more skeptical sense than an adherent of those traditions might offer (Friedman 2002). Where a rational empirical science might take religious beliefs as

informational constructs, and a social science might view them as social constructions, a transpersonal approach is more likely to understand them as reflecting not only information and societal creations, but also as responses arising from engagement with some phenomenon that has ontological presence in the world and warrants study. For example, some transpersonal scholars postulate that mystical experiences are not merely distortions of reality, but may reveal something about the cosmos not grasped in more mundane states of mind (Grof 1983; Tart 2000). States and processes such as meditation and enlightenment are considered possible avenues to other ways of knowing. Yet works within transpersonal studies typically step back from any particular tradition, seeking to evaluate spiritual and similar experiences in a frame that understands them as potentially valid parts of the whole person and the cosmos.

Characteristics

Transpersonal studies is most distinctive in its scholarly orientation of granting legitimacy to studying not only various states of consciousness, but also to studying them from the vantage point of various states of consciousness (Hartelius and Friedman 2010; Tart 2000). This is distinct from other scholarly traditions that tend to adopt a dispassionate and rational perspectives, whereas transpersonal studies considers ordinarily assumed divides, such as between the scholar and the object of study, and approaches, such as assumed rationality as opposed to intuitive or transrational approaches, to be artificial constraints. This is particularly apropos to the study of human beings in relation to diverse forms of spirituality and extraordinary experiences. Whereas traditional social science disciplines examining these topics (e.g., mainstream anthropology, psychology, and sociology of religion and spirituality) also explore the complexities pertaining to such phenomena, they are usually more focused on demographics and other etic variables, typically derived and interpreted according to academic frameworks that

hold narrower assumptions regarding reality (ontology), how we can know reality (epistemology), and human potential (what there is to know) (Hartelius and Friedman 2010). In contrast, transpersonal anthropology, psychology, and sociology consider that topics such spiritual experiences may offer valid glimpses into some things that are in some senses as real or possibly even more real than what conventional understanding through ordinary ways of knowing can grasp (Laughlin 1989; Grof 1983). For a transpersonal perspective, these do not necessarily represent distortions of reality so much as they may present aspects of reality that are difficult to grasp from within more ordinary states of consciousness, therefore requiring an emic approach. Transpersonal studies argue for the inherent value of certain types of non-ordinary experience on their own terms without reducing them to other ways of knowing (Laughlin 1989; Hartelius and Friedman 2010; Tart 2000). In addition to the transpersonal social sciences, other areas of transpersonal studies, such as art history and literary criticism, share this common framework for understanding and approaching their topics, but as humanities disciplines rather than as social sciences.

During its early decades, many transpersonal scholars subscribed to a perennialist philosophy, which attempted to understand various spiritual traditions as culturally situated reflections of a single and uniform transcendent reality (Grof 1983; Maslow 1969). However, Ferrer's incisive critiques of perennialism and his introduction of participatory philosophy into transpersonal theory have significantly shifted the debate within the movement to one of appreciating diversity in what is studied and how it is studied (Brooks 2010; Ferrer 2002). Perennialism attempts to perceive a singular ultimate within the world's spiritual traditions – an approach that can be illustrated by the metaphor that all rivers lead to the ocean. Participatory philosophy, by contrast, celebrates the diversity of traditions, and has been represented by the metaphor of an ocean with many shores. Transpersonal studies now typically accepts that, in order to understand the whole person in the context of global human

culture, no single frame of reference can account for all dimensions. The emphasis is therefore on employing multiple philosophical frames of reference as well as diverse research methodologies. Perennialism continues to function as a major framework, but as only one among several competing frameworks and it no longer has authoritative status.

Transpersonal studies provides not just a postmodern orientation that abandons its rootedness in traditional modern assumptions (Brooks 2010), but rather strives to be a post-Newtonian and post-Cartesian approach as well (Grof 1983). Modernism focuses on knowing an objective world; postmodernism addresses the many and different subjectivities by whom that world is known, and their impact on knowledge (Brooks 2010). Both preserve the rather large gap between subjectivity and objectivity that was articulated by Descartes in the seventeenth century, and neither challenges the mechanistic views that Newton's subsequent work has fostered (Friedman 2002; Grof 1983). It is this gap that transpersonal studies seek to address. Early perennialist models attempted to bolster the validity of transformative inner experiences by suggesting that, despite cultural differences in expression, spiritual traditions represent culturally-conditioned reflections of a singular transcendent reality. The notion that there may be spiritual realities that are empirically real in some ontological sense, yet inaccessible to ordinary sensory examination and unable to be studied scientifically, is entertained. Later participatory thought understands reality in more relational terms, where the world is not so much an objective space to which the subjectivity of human experience is an exception, as an intersubjective domain (Ferrer 2002). Differing spiritual traditions do not reflect aspects of some transcendent singularity as much as they embody the different ways that various cultural groups have co-created paths to deeper connection with the life of the larger whole. Participatory philosophy, though only developed in a preliminary way, resonates with more developed philosophical and psychological models that are based on systems thinking rather than

mechanistic models (Grof 1983), and evidences one direction in which transpersonal studies is heading.

Relevance to Science and Religion

Transpersonal studies is engaged with the heart of the debate concerning how science and religion can be understood within a frame that preserves the efficacy of both, though its focus is more on how spiritual, mystical, and other non-ordinary experiences can be studied scientifically without either reifying them or reducing them to the status of delusions (Friedman 2002); it is also concerned with how these can be appreciated from within the humanities tradition in a broadened way. It is interested in how the results of this study may provide a shifted framework within which to understand the mind, human society, culture, and personal and social relationships. In these endeavors, transpersonal studies wrestles with the epistemological divides between science and religion, and between one religion and another. One of the more helpful tools in the transpersonal approach is the notion that state of consciousness is a significant variable in comparative religion or philosophy: that different assumptions about reality may themselves be situated in different states of mind, and can best be understood from within those respective states of consciousness (Laughlin 1989; Tart 2000). This reflects a position that there is no single state of consciousness that has normative access to reality.

Sources of Authority

Transpersonal studies exist and develop within the current academic environment. Much transpersonal research is published in peer-reviewed journals such as *Journal of Transpersonal Psychology*, *International Journal of Transpersonal Studies*, *The Humanistic Psychologist*, *Journal of Humanistic Psychology*, *Transpersonal Psychology Review*, *ReVision: A Journal of Consciousness and Transformation*, and *Anthropology of*

Consciousness. While recent scholarship builds on previous scholarship, some early papers published by luminaries within the field such as Maslow and Grof are still referenced as important conceptual formulations (e.g., Grof 1983; Maslow 1969). For some years Ken Wilber was a particularly influential figure but, after his shift from transpersonal to integral psychology, the transpersonal field has been led by more diverse voices. Thinkers whose writings have contributed to the development and academic acceptance of transpersonal ideas include William James, Carl Jung, Otto Rank, Roberto Assagioli, Viktor Frankl, Abraham Maslow, Ken Wilber, Stanislav Grof, Stanley Krippner, Charles Tart, Roger Walsh, and Michael Harner.

Some accredited U.S. schools offering opportunities to study Transpersonal Psychology at the doctoral level include the Institute of Transpersonal Psychology/Sofia University, California Institute of Integral Studies, and Saybrook University. Many more opportunities are available worldwide to study transpersonal psychology at the master's level, or as an undergraduate course. The British Psychological Society has had its own Transpersonal Psychology Section since 1996 and, in the United States, the American Psychological Association Division of Humanistic Psychology (Division 32) is home to a Transpersonal Psychology Interest Group. Transpersonal Psychology and Humanistic Psychology are increasingly seen as complementary, such that to be fully humanistic requires recognizing the transpersonal while, conversely, to be transpersonal requires being first grounded in humanistic concerns. The Society for the Anthropology of Consciousness has been a division of American Anthropological Association since 1989.

Ethical Principles

Transpersonal studies is guided by the ethical principles of the scientific community with respect to research, the psychotherapy community's various ethical positions concerning clinical assessment and intervention, the values of the humanistic approach that opposes the reduction

of human experience to mechanistic processes, and the explicit transpersonal respect for the validity of experiences that may be situated within non-ordinary states of consciousness (Friedman 2002; Daniels 2005; Hartelius and Friedman 2010; Grof 1983; Maslow 1969).

Key Values

Key values of transpersonal studies include respect for human dignity, and respect for the interconnectedness of life and all of the cosmos. The first of these values it inherits from humanistic psychology, which holds as a central tenet that the present-moment experience of a living person cannot and should not be reduced to mechanistic components (Maslow 1969). Humanistic psychology, in turn, draws on the gestalt psychology tradition in this insight that the wholeness of human experience cannot be adequately represented by breaking it down into constituent parts. The second value obtains more from perceptions derived from spiritual and mystical experience, as well as from phenomenology, which assert that the world is a living unity, and that any division into discrete objects, however utilitarian, is to some degree an artificial construction imposed on an undivided whole.

The interconnectedness of the world, though in some respects a simple proposition, touches on complex issues, for interconnectedness is not a mere opposite to the view that the cosmos is made of discrete bits of matter. Rather, there can be many gradations of interconnectedness, ranging from the trivial notion that objects are always impacted by some parts of their environment, to the more radical notion that what appear as separate objects are in various senses inseparable from their context: Even an individual's sense of self and agency, though real, are shaped by the social, cultural, and geographical container within which they occur.

There is also a related but significantly different teaching within the tradition of Advaita Vedanta, which asserts that all of reality is radically one; Advaita means "not two," a concept that is typically translated as nonduality

(Whitfield 2009). This singular reality, Brahman, has no parts, no extension in space, and no duration in time. All of the world that is available to the senses is an illusory projection of that singularity, and the only reality that these sense objects have is the one reality that is their source. This Advaita teaching concerning the oneness of reality does not refer to interconnectedness of the world, since interconnectedness of those phenomena would simply be a perceived quality within the illusory realm of sense objects. The importance of differentiating this point is that the nonduality of Advaita is at times incorrectly conflated with the quality of interconnectedness. Both positions are views that some transpersonal scholars hold, but the two should be understood as distinct from each other.

Conceptualization

Nature/World

Nature is understood as a living system with which humans are both part and inextricably interconnected. The world is not seen as a collection of mere physical particles under the effect of impersonal forces, but a matrix in which consciousness and compassion may also be present (Grof 1983). The dynamics of ecology mirror those of psychology, because mind and nature are not separate.

Human Being

The human being is understood as an aspect or facet of an interconnected living system (Hartelius and Friedman 2010). The appearance that people are separate, self-directed individuals is balanced by the insight that humans are intimately shaped – physiologically, mentally, and emotionally – within the relational network of the world (Brooks 2010). The limits of the ego are not the boundaries of the person, for an individual is capable of expanding beyond those bounds in both space and time, and perhaps in ways to which time and space have no relevance (Friedman 2002; Grof 1983). A transpersonal perspective posits a larger potential for the development of an individual beyond the conventional stages of sexual

and cognitive maturity achieved in early adulthood, holding the possibility of the ongoing cultivation and deepening of qualities such as empathy, compassion, wisdom, and altruism.

Life and Death

Life is the natural condition of the world, and death is seen as a possible transition to other forms of existence, not necessarily a terminus. Due to this orientation, transpersonal scholars have an interest in topics such as near-death experiences, after-death communication, research into reports of reincarnation, and other such areas of study related to phenomena that assume the possibility of some conscious survival of death (Hartelius and Friedman 2010; Grof 1983).

Reality

The nature of reality is a philosophical question, and transpersonal studies entertains a variety of philosophical approaches, including perennialist, participatory, postmodern constructivist, and critical realist. In this sense, transpersonal scholarship does not have a defined position on the nature of reality. What transpersonal perspectives typically have in common is a view that there is more to reality than a simple mechanistic or materialistic perspective can describe, and that spiritual, mystical, and some non-ordinary experiences may be related to the perception of phenomena that belong to this order (Grof 1983).

Knowledge

Knowledge can be either intellectual, conceptual, and theoretical representations of phenomena, in a standard academic sense, or it can be a process of relational engagement with the world that leads to a lived understanding. Knowledge does not have to be limited to a particular state of consciousness nor set of rules, such as linear logic, as knowing can be transrational. For example, deeply intuitive knowledge can be how a part might immediately know the whole by virtue of being connected from the inside to the whole, rather than through an external way of knowing that is divided between subject and object (Anderson and Braud 2011; Friedman 2002).

Truth

Transpersonal studies is divided on the issue of truth. Those scholars holding to a perennialist philosophy tend to conceive of truth as pertaining to a transcendent spiritual dimension, whose verities are filtered down and variously distorted through different cultures (Ferrer 2002). Scholars more inclined to a participatory philosophy understand knowledge as arising in specific, located, and relational contexts, and do not imagine that there is a monolithic or authoritative truth to be obtained (Brooks 2010; Ferrer 2002).

Perception

In a transpersonal approach, the spectrum of perception is envisioned as containing more than the standard physical senses. It is often assumed that intuitive forms of vision, hearing, sensing, or knowing may also represent avenues of perception – though these may operate in association with states of consciousness that differ in some ways from states typical of ordinary rational thought (cf. Friedman 2002).

Time

There is little transpersonal scholarship that addresses the conceptualization of time, though the concept of transpersonal self-expansiveness beyond the ego can represent expansions into the past and future, as well as a spatial expansion (Friedman 2002).

Consciousness

Transpersonal scholars are more unified in what they reject about consciousness than in what they allow. Consciousness is seen as something more than an epiphenomenal product of material interactions (Grof 1983; Maslow 1969). Consciousness may be the matrix out of which matter arises, or perhaps consciousness is an intrinsic property of matter.

Rationality/Reason

Reason is held as an important standard of mental discipline. However, in contrast to the Enlightenment perspective that imagines a complete knowledge of the world can be obtained by applying the rational mind to the study of the

objects of the world, transpersonal scholars typically recognize that the nature of the world is something more than a simple physicalism might allow. For this reason, deep understanding of the world may require reason at a minimum, but phenomena may also carry a complexity that demands something more than reason alone – some intuitive grasp of pattern or resonance (Friedman 2002; Grof 1983). Knowledge based on exercises of this sort should then be tested in reasonable ways, employing methods that are capable of testing for the possible presence of more subtle or complex patterning, and do not reduce the phenomena based on assumptions that only simple physical mechanics are operant (Anderson and Braud 2011).

Mystery

For transpersonal scholars, mystery typically refers to aspects of the world that are not grasped by a mechanistic or materialistic account of reality, but are directly encountered within experiences related to the practice of mysticism (Friedman 2002; Grof 1983).

Relevant Themes

The emic/etic distinction, derived initially from debates related to anthropological research, pertains to a group or individual's differing perception of reality structured according to a particular cultural background or experiential knowledge. Today it is often considered that an emic account belongs to someone "native" to a culture, while an etic account belong to that of a cultural outsider. This important distinction can also be applied to alternate states of consciousness, which can be difficult to understand if not actually experienced in an emic way (Laughlin 1989; Tart 2000). It would be difficult, if not impossible, for an investigator to provide a neutral etic account, as it would be for a cultural "native" to be able to formulate an emic account, because all are biased by their own worldview. The emic/etic distinction is extremely relevant when investigating transpersonal experiences related to particular cultural

and religious backgrounds of a studied participants. Such difficulties in doing transpersonal studies may require considerable redefining of what it means to be human related to cultural divides and various alternate states, such as springing from psychedelic experiences or immersion in cultures with radically differing worldviews.

Description

The concept of truth is one of the most widely discussed concepts in modern philosophy. And understandably so, for “truth” is what philosophers, scientists, theologians, etc., typically (or at least often) understand themselves to be aimed at pursuing. And not only so, even nonpractitioners of philosophy, science,

theology, etc., also typically take themselves to pursue truth. Indeed, the concept of truth seems more or less to permeate the whole of human culture. What, then, *is* this thing called truth? In what follows, we will survey some sustained and much-discussed philosophical attempts to answer this question, with a focus on Western thought in general and on analytic philosophy in particular.

The Classical Heritage

Two simple but immensely influential characterizations of the notion of truth in traditional Western thought are those of the Greek philosopher Aristotle (384–322 BC) and the scholastic philosopher Thomas Aquinas (1225–1274). Taken together, these two characterizations could be regarded as providing something of a “classical heritage” in Western thinking about truth.

Aristotle’s (1968) characterization of the notion of truth (*aletheia*) is found in his *The Metaphysics* IV and VIII, and consists in the claim that “to say” (*legein*) that “what is is, and what is not is not, is true” (*to on einai kai to me on me einai alethes*). This characterization relates two things to each other: reality (“what is,” “what is not”) and speech (“to say”). The way in which reality and speech are related to each other is left implicit but is clearly understood as some sort of congruence.

Thomas Aquinas’ (1948) characterization of the notion of truth (*veritas*) is found in his *Summa Theologica* I, q16, a2 (as well as in *De veritate* q1, a2). Thomas draws on Aristotle’s characterization but goes two steps further than Aristotle. A first step consists in explaining truth not via a relation between reality and speech but rather between reality and mind (*intellectus*). A second step consists in explaining the relevant relation between reality and mind as a relation of conformity or adequation (*adaequatio*). The resulting characterization runs: “Truth is the conformity of thing and intellect” (*veritas est adaequatio rei et intellectus*).

Aristotle’s and Thomas’ characterizations of truth are usually described as “correspondence

theories of truth,” but one does well to bear in mind that neither Aristotle nor Thomas spoke of their characterizations as “theories,” nor did they seek to shed light on the relevant relation between reality and speech/thought by means of the term “correspondence” (this term was not used in mainstream philosophical theorizing about truth until the early twentieth century).

Correspondence Theories

The most well-known and discussed type of theory of truth is the correspondence theory of truth. This type of theory comes in many different versions. Perhaps the two most famous attempts to develop correspondence theories of truth in modern analytic philosophy are those of Cambridge philosopher Bertrand Russell (1872–1970) and Oxford philosopher John L. Austin (1911–1960) to which we now turn.

In *The Problems of Philosophy* ([1912] 1998), Russell proposes three “requisites” which he holds that all theories of truth must fulfill. A first requisite is that the theory of truth recognizes that truth and falsity are properties of beliefs; accordingly, a theory of truth developed along strictly materialist lines will not work. A second requisite is that the theory recognizes that truth and falsity “always depend upon something which lies outside the belief itself” ([1912] 1998, 70). A third requisite is that the theory admits not only of truths but also of falsehoods; in other words, a theory of truth that entails that there are only truths and no falsehoods must be wrong. Russell regards these three requisites as fairly obvious.

Russell’s attempt to develop a theory of truth that meets the above requisites can be summarized as follows: In line with the first requisite, it is proposed that the things that are true or false are beliefs or judgments understood as essentially involving minds. In line with the second requisite, it is proposed that a true belief or judgment is one in which a mind judges certain objects in the world to be arranged in a certain order, and these objects really are arranged in this order in the world. Given this, the first requisite can also

be seen to be capable of being met for a false belief or judgment can then be said to be a belief or judgment in which a mind judges certain objects to be arranged in a certain order, and these objects are not actually arranged in this order in the world (See Russell [1912] 1998, 69–75).

Austin's theory of truth is put forth in his influential paper "Truth" ([1950] 1961) and differs in many ways from Russell's theory. Contrary to Russell's first requisite, Austin does not take beliefs but statements to be the primary bearers of truth and falsity on the ground that beliefs are beliefs in things that have or can be stated. Crucial to Austin's theory are two pairs of distinctions: first, a distinction between sentences and statements and second, a distinction between types of states of affairs and historic states of affairs. What these distinctions amount to can be explained by the following example: the sentence "the cat is on the mat" has one meaning but can be used to make various different statements, for example, the statements that the cat in Tom's house is on the mat, that the cat in Sally's house is on the mat, and so on. The state of affairs that this sentence picks out is not an actually obtaining state of affairs but rather a type of states of affairs, whereas the particular states of affairs corresponding to the statements that the cat in Tom's house is on the mat, that the cat in Sally's house is on the mat, and so on, are not types of states of affairs but allegedly obtaining, historic, states of affairs. Given these distinctions, Austin now proposes the theory of truth, roughly put, that a statement is true when the historic state of affairs which it picks out is "of a type with" or "sufficiently like" the type of state of affairs picked out by the sentence by means of which the statement is made; if the historic state of affairs is not sufficiently like the relevant type of state of affairs, the statement is false (Austin [1950] 1961, 89–90).

Russell's and Austin's theories are similar to each other in that they both take for granted that there are such things as arrangements of objects, or states of affairs, in the world. They are also similar to each other in that they propose that the truth or falsity of beliefs or statements is to be

explained via reference to these arrangements of objects or states of affairs in the world. It is on account of this last similarity that the two theories are usually dubbed "correspondence theories of truth."

Correspondence theories of truth of the above and other sorts have attracted widespread sympathy, especially from analytic philosophers. But they have also been much criticized. One of the most discussed objections in recent years is the so-called slingshot objection; according to which, the admittance of a plurality of states of affairs entails that there can be only one state of affairs. The arguments adduced in support of this alleged entailment are often very complex, however, and also highly controversial.

Two Tarskian Contributions

In the 1930s and 1940s, the Polish logician Alfred Tarski (1902–1983) made some celebrated contributions to discussions of truth. These contributions were taken by Tarski to provide "a more precise expression" of the "intuitions" underlying "the classical Aristotelian conception of truth" ([1944] 1996, 342–343). Of Tarski's various contributions, two have stood out as especially significant.

A first such contribution consists in Tarski's proposal of a criterion for the adequacy of any theory of truth that is to count as explicating the classical Aristotelian notion of truth. The criterion runs, thus, "X is true if and only if *p*," where "X" stands for the name of a sentence and "*p*" stands for the sentence thus named ([1944] 1996, 344). This is Tarski's well-known "criterion of material adequacy," or "Convention T." The sentence "Snow is white," for example, counts as true if and only if snow is white and so on for all other (declarative) sentences. Tarski argues that the application of this criterion to natural languages such as English generates logical contradictions. The sentence "This sentence is false," for example, will be true if and only if the sentence is false. In view of this result, Tarski draws the radical conclusion that a consistent definition of truth within the context of natural languages is – at least by present lights – impossible.

A second significant contribution of Tarski's consists in the proposal of a definition of truth in the context of formal logical languages. The proposed definition makes use of a distinction between object language and metalanguage; the object language contains, among other things, the linguistic expressions of a formal logical language that are used to refer to objects in the world (typically first-order variables, singular terms, and n -place predicates), whereas the metalanguage consists of various linguistic expressions used to talk about the linguistic expressions of the object language. On the basis of this distinction, Tarski sets as his aim to provide a definition on the metalanguage level of the truth predicate "x is true" as it occurs on the object language level. This is done via the logical notion of *satisfaction*. Tarski offers a detailed and technically rigorous definition of satisfaction, but on the more general level, the notion can be described as a certain sort of relation between objects and linguistic expressions, where, for example, an object a is said to satisfy a predicate such as "x is white" if and only if a is white. The truth or falsity of a sentence of a formal logical language is then defined in terms of an object sequences satisfying the sentence or not satisfying the sentence. The resulting definition can be shown to be materially adequate in the sense of abiding by the above mentioned Convention T. Moreover, inasmuch as the object language does not contain the linguistic resources required for talk about its own sentences, the application of Convention T to this language does not generate contradictions.

Tarski's two above contributions have enjoyed much respect and prestige, especially among analytically oriented philosophers. But there have also been critics. With regard to Convention T, it has been urged that this criterion is philosophically trivial and is fulfilled by any and every theory of truth. With regard to Tarski's definition of truth in terms of satisfaction, it has been urged that this definition sheds no light on the notion of truth as discussed by traditional philosophers for traditional philosophers have not been concerned with defining a truth predicate that figures in a formal logical language but

with understanding the notion of truth at play in natural language and ordinary thinking. On a more general level, it has been urged, with regard to both Convention T and Tarski's satisfaction definition of truth, that they fail to shed light on the notion of truth inasmuch as truth is a value not of sentences but of the objects of propositional attitudes such as beliefs, disbeliefs, doubts, and so on – that is, of propositions.

The Deflationist Thesis

A much-discussed theory of truth in recent literature is deflationism whose chief contemporary elaboration is found in contemporary philosopher Paul Horwich's book *Truth* (1990).

The core claim of deflationism is the thesis that the meaning of the truth predicate is adequately and fully captured by instances of the so-called equivalence schema: "The proposition p is true if and only if p " (not to be confused with Tarski's Convention T, which states necessary and sufficient conditions for the truth of sentences, not of propositions). Instances of this schema are "the proposition *that snow is white* is true if and only if *snow is white*," "the proposition *that the cat is on the mat* is true if and only if *the cat is on the mat*," and so on. Since the list of instances of the equivalence schema is infinite, it is not possible to state the deflationist theory exhaustively; one can only give partial statements of the theory by lists of instances of the equivalence schema of the above sort.

Another central thesis of deflationism is that there is nothing more to the content of the term "true" than what is captured by instances of the equivalence schema. Traditional philosophy's quest for a definition or theory about truth that is to tell us more about truth than is captured by instances of the equivalence schema is considered fruitless and confused: there is simply nothing more to know about the meaning of "true" than is found in these instances.

The above position naturally gives rise to the question why there is a truth predicate in natural languages such as English in the first place. For, after all, "the proposition that p is true" says no

more than “*p*”; why then make use of the truth predicate at all? Horwich’s response is that the truth predicate functions as a sort of referential device enabling us to do such things as refer to propositions the contents of which we are not clear about. For example, the truth predicate enables to say that “what Tom said is true” even if we are not clear about what Tom actually said. These sorts of locutions would not be possible if we only could refer to what Tom said by repeating what he actually said hence the utility of the truth predicate in natural languages.

Like all truth theories, the deflationist theory has received its share of criticism. An important objection to the theory is that it fails to tell us what all true propositions have in common, which, it is felt, a theory of truth ought to be capable of telling us. The deflationist theory only tells us what it means for specific propositions to be true, not what all these true propositions have in common.

The Indefinability Thesis

According to a further approach, which shares with deflationism a rejection of substantial theories of truth, truth cannot be defined at all but should instead be regarded as a primitive or indefinable notion. A major representative of this approach in the analytical philosophical tradition is the German philosopher-logician Gottlob Frege (1848–1925).

In “Der Gedanke” (1918), Frege seeks to support the thesis that truth is indefinable by means of the following argument. With regard to any proposed definition of truth, it can always be asked whether that definition is true, in which case the notion of truth will already be involved in the definition in question. Take, for example, the proposal that truth consists in the correspondence of a proposition with a fact. With regard to this proposal, we can ask whether the proposal is true or not, and it is only in the case of the proposal being true that it will succeed in telling us what truth is. But if this is so, then the notion of truth will already be presupposed in its definition. And this result naturally extends to all proposed

definitions of truth. All definitions of truth, Frege concludes, must be circular.

A possible objection to Frege’s argument for the indefinability thesis is that definitions, strictly speaking, are not the sort of things that can be true or false. If a “true proposition” is defined as, say, “a proposition that corresponds to a fact,” then this definition merely fixes the meaning of the term “true proposition,” and this fixing of meaning is not something that can be true or false. To this objection, it might be responded that Frege’s argument is really aimed at undermining definitions that seek to provide true-or-false explications of the concept of truth, not at definitions that fix the meaning of a term. The cogency of Frege’s argument would seem to depend on the adequacy of this sort of response.

Practical and Epistemic Constraints

There have been various twentieth-century attempts to put practical, epistemic, or other kinds of restrictions on truth. In what follows, we briefly survey some of these restrictions:

Practical restrictions on truth were famously introduced by William James (1842–1910) and other so-called American pragmatists. In *The Meaning of Truth* (1909), James claims that true ideas are “those that we can assimilate, validate, corroborate and verify,” or that which is “expedient in the way of our thinking” (1909, 3–4). Otherwise put true propositions are true only insofar as they have certain practical consequences.

Practical restrictions on truth of the above sort have on the whole been rejected by analytic philosophers. There seem to be numerous obvious counterexamples to such restrictions. Take, for example, proposition events in the far past. Surely, it may be true or false that Julius Caesar’s grandmother was born at 1 o’clock, but it is unlikely that it makes any practical difference to us either way. And so on for various other propositions about the distant past.

More recently, Oxford philosopher Michael Dummett (1978) and Harvard philosopher Hilary Putnam (1981) have argued that there is a strong

conceptual tie between truth and justifiability, such that for any truth p it is the case that p can be justified, if not in practice, then at least in principle, in ideal epistemic conditions, by an ideally rational community or suchlike. An important consequence of this position is its antimetaphysical thrust: there can be no such thing as a proposition whose truth value is in principle inaccessible to human beings.

Dummett and Putnam both argue for their above point of view by means of various meaning theoretical considerations. Dummett's main argument proceeds from the idea that since the meaning of terms is derived from their use, the meaning of the term "true" must manifest itself in some actual linguistic use, to wit, in the capacity to decide whether propositions are true or not. Such a manifestation would not be possible in the case of propositions whose truth values could not be decided, however; hence, there cannot be such propositions (see Dummett 1978, 215–247). Putnam's main argument is that the idea that there are propositions whose truth values are inaccessible to human minds presupposes the further idea that the world consists of a fixed totality of mind-independent objects. But this further idea, argues Putnam, does not ultimately make sense for the only objects we could possibly talk about in any meaningful sense are the objects that present themselves in human experience and conceptualization and hence are not mind independent (see Putnam 1981, 1–74).

Dummett's and Putnam's epistemic restrictions on truth have attracted enormous attention within analytic philosophy but also widespread criticism.

A major objection to Dummett's above-considered "manifestation argument" (as it has been called) for epistemic restrictions is that there are various other ways in which knowledge of the meanings of terms could manifest itself in actual linguistic use besides the capacity to decide whether sentences or propositions are true or not. For example, such knowledge could manifest itself in the ability to use the relevant terms as they are ordinarily used in a natural language, for instance, by being able to combine them with each

other in appropriate ways to form meaningful sentences.

A major objection to Putnam's argument is that the objects that we can meaningfully talk about are by no means limited to objects that present themselves in human experience. Natural languages typically contain various resources – for example, various descriptive devices such as so-called definite descriptions – enabling talk also about objects lying beyond human experience, such as abstract objects (numbers, sets) or quantum particles (electrons, quarks).

More generally, it has been urged against Dummett/Putnam-style epistemic restrictions on truth that these restrictions, just like the practical restrictions familiar from pragmatists such as James, are unable to account for the fact that there are obviously true-or-false propositions about the distant past which nevertheless fall beyond the range of what can be true or false according to the proposed restrictions. Thus, given Dummett's and Putnam's epistemic restrictions, a claim like "Julius Caesar's grandmother was born at 1 o'clock" would seem to be incapable of being true or false since there seems to be no way of verifying it; but clearly, this claim is either true or false, and accordingly, Dummett/Putnam-style epistemic restrictions must be mistaken. For these sorts of reasons, many contemporary philosophers have rejected epistemic constraints on truth and have embraced the opposing idea that there can be propositions whose truth values lie beyond what human beings can find out.

Context-Dependent Approaches

According to some philosophers, the concept of truth should be understood in different ways depending on the context or subject matter in which it figures. Thus, for example, mathematical propositions might be true in the sense that they can be proved within some mathematical system, scientific propositions might be true in the sense that they accurately describe the world, and theological propositions might be true in the sense that they somehow are true to one's existential experience. This view is particularly popular

among philosophers influenced by Ludwig Wittgenstein and has been applied particularly to religious themes such as belief in God. Thus, D. Z. Phillips (1934–2006), the preeminent twentieth-century Wittgensteinian philosopher of religion, says that belief in God is “a matter of what to make of life itself” and is as such not a belief “whose truth depends on whether it tallies with the facts” (Phillips 2004, 85).

A common argument urged in support of the present context-dependent approach to truth derives from Wittgenstein’s dictum that the meaning of a term consists in its use. In line with this, it has been said that in order to know what the term “true” means when applied to the propositions of some particular context or with regard to a particular subject matter, one has to look and see how it is used in the particular context or subject matter in view. Once one does this – it is often claimed – it will often be clear that the term “true” as it figures in one particular context means something different from its occurrence in another context. For example, in religious contexts, the term “true,” as applied to, say, the belief that God exists, does not mean anything like “describes reality accurately,” which may be what the term means in the natural sciences. In religious contexts, the term “true” may instead mean something more like “existentially adequate” or suchlike. And the same goes *mutatis mutandis* for uses of the term “true” in numerous other contexts.

Critics of the present context-dependent approach to truth have urged that there is only one concept of truth and that all subject matters – mathematics, the sciences, theology, and so on – are all concerned with arriving at truth in this one sense of “true.” In support of this claim, it has often been said that this is how people in these various different contexts understand themselves to be using the term “true.” The person who wants to know whether it is “true” that God exists is not using the word “true” in a different sense from the person who wants to know whether it is “true” that numbers, sets, quarks, or electrons exist even though the importance attached to the former question is often considered far greater than the importance attached to the latter ones.

Truths, Four Noble

Bhikkhu Anālayo

Center for Buddhist Studies, University of Hamburg, Hamburg, Germany

Related Terms

[Ariyasacca \(Pāli\)](#); [Aryasatya \(Sanskrit\)](#)

Description

The four noble truths are perhaps the most central teaching of Buddhism, delineating the scope of *dukkha* – a term whose meaning ranges from barely noticeable dissatisfaction to outright

suffering as inherent features of human existence (► [Dukkha](#)) – the arising of *dukkha*, its cessation, and the path leading to its cessation.

What makes these four noble truths particularly relevant to the dialogue between science and religions is the circumstance that the Buddhist discourses correlate the four aspects of this scheme with four qualities of medical practice. This comparison is based on the notion that a doctor needs to be able to identify a disease, diagnose its cause, know what constitutes the appropriate remedy, and administer the medicine until the disease is cured (Takakusu and Watanabe 1924–1934, 2.105a and T 2.462c). In other words, this central doctrine of Buddhist thought conceptualizes the human predicament of *dukkha* in terminology reminiscent of medical analysis. The underlying pattern of the four noble truths could thus be represented as follows:

- Disease: *dukkha*
- Pathogen: craving
- Health: Nirvāṇa
- Cure: noble eightfold path

In this way, while the first noble truth recognizes the nature of the “disease” of *dukkha*, the second noble truth identifies craving as the pathogen responsible for the arising of *dukkha*. The third noble truth then envisages the realization of Nirvāṇa as the condition of health wherein *dukkha* ceases, and the fourth noble truth delineates the eightfold path as the actual cure whose undertaking will lead to realizing the cessation of *dukkha*.

According to tradition, this form of presentation was adopted by the Buddha right after his awakening in order to convey what he had realized to those who were to become his first disciples (Feer 1884–1898, V 421). The four noble truths can thus be considered as the Buddha’s teaching in a nutshell. A simile in fact compares the comprehensiveness of these four noble truths to the footprint of an elephant, which due to its size comprises the footprint of any other animal (Trenckner and Chalmers 1888–1896, I 184).

The scope of *dukkha*, according to the first noble truth, covers physical events such as disease and death, as well as the mental displeasure that can arise from being unable to satisfy

one’s desires. The first noble truth then sums up its description of *dukkha* under the chief fact of the five aggregates (affected by) clinging. These five aggregates are considered in early Buddhist thought as the chief constituents of an individual, comprising bodily form, feeling, perception, volitional reactions, and consciousness. Thus, *dukkha* can in the final count be traced back to clinging to various aspects of oneself. In other words, the actual experience of *dukkha* requires personal involvement in what is taking place by way of clinging, attachment, and craving.

The second noble truth identifies craving as the chief condition for *dukkha*, glossed as the tendency to delight in this and that. A more detailed exposition of the genesis of *dukkha* takes place by way of dependent arising, which has ignorance as the starting point (► [Dependent Arising](#)). This provides the backdrop to the idea that craving is the chief culprit for the predicament of *dukkha*, in that any reaction by way of craving is itself the conditioned outcome of ignorance.

The cessation of ignorance then leads via the cessation of craving to the cessation of *dukkha*, the theme of the third noble truth. Such cessation finds its consummation in the four levels of awakening recognized in early Buddhism: stream entry, once return, nonreturn and arahantship (► [Awakening](#)).

The fourth noble truth presents the noble eightfold path as the means for reaching Nirvāṇa and the cessation of *dukkha*. This path covers the eight central requirements for achieving full awakening:

- Right view
- Right thought
- Right speech
- Right action
- Right livelihood
- Right effort
- Right mindfulness
- Right concentration

Right view in this context is an appreciation of the four noble truths, in that such a type of view sets the direction and context for any undertaking of the path. In other words, rightly directed view is the precursor of the other factors of the path (Trenckner and Chalmers 1888–1896, III 71).

Based on right view, the practitioner then develops right thought by leaving behind thoughts of sensual desire, ill will, and harming, instead engaging in their opposites. With right speech, right action, and right livelihood, the necessary moral foundation for progress to awakening is brought into being. This requires avoiding falsehood and other types of unwholesome speech, as well as refraining from actions like killing, stealing, and sexual misconduct, and not adopting a type of livelihood that involves inflicting harm on others.

Right effort then stands for endeavoring to overcome unwholesome mental conditions and establish what is wholesome in the mind. Right mindfulness covers contemplation of the body, feelings, mental states, and phenomena in an attempt to understand their true nature. With right concentration, the development of mental tranquility comes to the fore, expressed in terms of four levels of absorption (Sanskrit *dhyāna*, Pāli *jhāna*), during which the mind becomes deeply concentrated and internally stable.

According to a stanza found in an early Buddhist collection of poetry, gaining insight into these four noble truths will provide the practitioner with a supreme refuge, far preferable to any sacred place or other type of refuge (von Hinüber and Norman 1994, Stanza 192).

[Models of how to relate science and religion](#)

Barbour's Typology

The most influential typology of how to relate science and religion has been developed by Ian Barbour.

Barbour proposes a fourfold taxonomy (conflict, independence, dialogue, and integration) in order to give a systematic overview of the main options today. Advocates of Barbour's first view, the *conflict view*, maintain that science and religion are rivals. They compete on the same turf, and in the end, one will emerge as the winner. His two paradigm examples of advocates of the conflict view are scientific materialists (or proponents of scientific naturalism or scientism) and religious literalists: "They both claim that science and theology make rival literal statements about the same domain, the history of nature, so that one must choose between them" (Barbour 1997: 79). Defenders of the *independence view*, on the other hand, maintain with regard to science and religion that each has its own distinctive domain and its characteristic methods that can be justified on its own terms. Proponents of this view say there are two jurisdictions and each party must keep off the other's turf. Barbour also identifies two mediating positions between these extremes. The advocates of the *integration view* hold that some sort of integration is possible between the content of theology and the content of science (Barbour 2000:3). Thus, for example, proponents of this view could maintain that changes in scientific theories may affect the reformulation of certain religious beliefs (such as ideas about creation, original sin, and divine omnipotence). Barbour maintains that in the fourth model, the *dialogue view*, a less direct relationship between science and religion than that posited in the integration view, is defended. Although an exchange between the two practices may take place about the metaphysical presuppositions, the methods, or the conceptual tools of science and religion, in contrast to the integration view reformulation of the content of science or religion will seldom be called for.

Barbour's typology can be summarized in the following way:

1. *The conflict view* is the view that science and religion are rivals; they compete on the same turf, and in the end, one will emerge as the winner.
2. *The integration view* is the view that there is some sort of overlap between science and religion so that changes in scientific theories may entail the reformulation of religious beliefs or doctrines.
3. *The dialogue view* is the view that an exchange between science and religion can take place about metaphysical presuppositions, methods, conceptual issues, and the like, but it would not or at least seldom result in a reformulation of religious beliefs or doctrines.
4. *The independence view* is the view that science and religion each has its own distinctive and completely separate domain.

Due to its influence among scholars in the science-religion field, Barbour's typology has also been the object of criticism (Cantor and Kenny 2001: 765f).

One problem is that Barbour sometimes writes like three of these science-religion views are compatible with each other, but they are not. It is true that it is compatible with both the dialogue view and the integration view that something is valid in the independence view because if one maintains that there is merely an intersection between science and religion, then this entails that some part of religion is independent of some part of science. However, as soon as there is an overlap in respect to methodology, then this is not compatible with the independence view because by definition, it contains the claim that there are no overlaps between science and religion. Moreover, if there is an overlap with respect to the doctrines of creation and human nature, then this undermines the dialogue view because it presupposes that the overlap is limited to methodology, conceptual issues, boundary questions, and the like. One can advocate only one of these views because they are defined as mutually excluding each other.

A second problem concerns the names Barbour gives to two of these views: "integration" and "dialogue." Irrespectively of which of these science-religion views we hold, we could

argue that its advocates ought to become engaged in a *dialogue* with each other and thus sometimes drop the polemics or stop ignoring each other. Dialogue is thus a way in which people that holds different views can relate to each other. It is therefore unfortunate and biased to call one science-religion view the “dialogue” view, because it could be argued that it is desirable that people, irrespectively of which of these views they hold, should at least sometimes try to become involved in a dialogue with each other and listen carefully to what people with different views think about these issues. To some extent, this is also a problem with “integration.” It seems as though we can talk about integration between two things only if we believe that both are worthwhile but different in some important respect. It does not make real sense to try to integrate science and religion if you think that only religion or only science is worthwhile.

Third, as soon as one allows an interaction between science and religion, one opens the door for potential conflict, consonance, or harmony between science and religion. Drawing on the recent work of astronomers, John Polkinghorne and others have argued that the physical constants in the early universe appear to be fine-tuned as if by design, thus providing additional confirmation for a belief in God as the designer and creator of the universe (Polkinghorne 1998). Religious practitioners could by religious ways of belief formation obtain this knowledge, but now, it seems as if information obtained by scientific ways of belief formation can also confirm this religious belief. However, not only does intersection between science and religion allows the possibility of harmony, it also allows the possibility of conflict. Gordon Kaufman for instance argues that changes in scientific theory make it necessary to reconstruct the conception of God that has traditionally been endorsed by Christians, Muslims, and Jews. There is a conflict between a personal conception of God and scientific theories about cosmic and biological evolution (Kaufman 2001). Nevertheless, Kaufman does not (in terms of Barbour’s typology) accept a conflict view: he holds an integration view. Here, we

have a more serious conceptual problem with Barbour’s typology. Even if a scholar engaged in the religion-science dialogue maintains that there is a conflict between science and religion, this does not automatically make him or her a proponent of the conflict view. *Conflict* between science and religion is compatible with the conflict view, the integration view, and the dialogue view. *No conflict* between science and religion is compatible with not merely the integration view and the dialogue view but also the independence view. Of course, the larger the intersection between science and religion is, the larger the area of potential conflict (or harmony for that matter) between science and religion is.

Haught’s Typology

John Haught has developed slightly different typology for how to relate science and religion than Ian Barbour. Haught, just like Barbour, proposes a fourfold typology (conflict, contrast, contact, and confirmation). Some hold that religion is utterly opposed to science or that science totally undermines religion. This is the *conflict view*. Haught gives a number of examples of scholars who hold this view. The historian of science William Provine writes that we have to check our brains at the church house door if we are to be both scientist and believer, and the physicist Steven Weinberg claims that the deeper science looks into the nature of things, the less the universe seems to bear any imprint of an interested God (Haught 1995: 12, 28).

The second approach is the *contrast view*. Its advocates insist that religion and science are so different from each other that they cannot come in conflict. They are both valid but yet completely separated domains with no overlap. Science is concerned with examining the natural world empirically, religion is a search for ultimate meaning and values. He takes for instance protestant theologians Rudolf Bultmann and Karl Barth to exemplify particular versions of this science-religion as well as theologians inspired by the later work of the philosopher Ludwig Wittgenstein.

Those who hold the *contact view* argues rather that although science and religion are distinct, science always has implications for religion and vice versa. The term “contact” implies coming together without necessarily fusing. Haught sees Ian Barbour, Ted Peters, and many other participants in contemporary science-religion dialogue as advocates of this view. According to the contact view, theologians always bring at least implicit cosmological assumptions to their talk about God. Theology should therefore remain positively consonant with cosmology, and the same applies to all the other sciences. Haught writes that the contact view “proposes that scientific knowledge can broaden the horizon of religious faith and that the perspectives of religious faith can deepen our understanding of the universe. It does not strive to prove God’s existence from science but is content simply to interpret scientific discoveries within the framework of religious meaning” (Haught 1995: 18). He prefers to collapse much of what Barbour in his typology calls “dialogue” and “integration” into this broader contact view.

The forth alternative is akin to but logically distinct from the third. Its spokespersons maintain that religion positively supports the scientific adventure of discovery. It looks for those ways in which religion, without in any way interfering with science, paves the way for some of its ideas and even gives a special kind of blessing to the scientific quest for truth. Haught states the view as follows: “religion’s claim that the universe is finite, coherent, rational, ordered totality, grounded in an ultimate love and promise, provides a general vision of things that consistently nurtures the scientific quest for knowledge and liberates science from association with imprisoning ideologies” (Haught 1995: 4). This is the *confirmation view*; religion does provide confirmation of the trusting that underlies science. Haught, following the theologian David Tracy, embraces this view himself and claims that it envisages a more intimate relationship of religion to science than the contact view.

Haught seems to acknowledge that the first three views are incompatible. People could not hold more than one of these at the same time.

However, his own view is that the contact view supplemented by the confirmation view provides the most fruitful and reasonable alternative of how to understand the relationship between science and religion. Hence, at least the last two views in the typology are not mutually exclusive but can (but need not) be combined.

Haught’s typology can be summarized in the following way:

1. *The conflict view* is the view that science and religion are fundamentally irreconcilable.
2. *The contrast view* is the view that religion and science are both valid but yet completely separated domains with no contact.
3. *The contact view* is the view that although science and religion are distinct, there could be dialogue, interaction, and possible consonance between the two domains.
4. *The confirmation view* is the view that religion on a deep level supports and nourishes the entire scientific enterprise, but it does not support and nourish particular scientific theories.

Haught believes that the confirmation view goes further than the contact view. Haught writes that he “appreciate all the efforts to discover consonance between science and religion” but he “envisage a more intimate relationship of religion to science” than the contact view (Haught 1995: 21). On this point, he can be criticized for giving a too narrow interpretation of the contact view. If it is meant to cover the ways of relating science and religion which are not to be classified as a version of the conflict view, the contrast view, or the confirmation view, Haught cannot take the contact view to be merely about discovering consonance between science and religion nor can he deny that an advocate of the contact view could attempt to prove or, which is more common, give evidential support for God’s existence by appealing to scientific data.

If the contact category is to be broader than Barbour’s dialogue and integration categories, then it must leave open what particular form of contact its defenders advocate. This category should cover not only those who argues for a more thoroughly positive contact than consonance but also those who claim that there is on some points conflict or at least tensions between

science and religion. So for instance, the philosopher Michael Ruse's view is that science and Christianity are two distinct and valid domains but that although it is possible to combine the two, it is not as easy as Christians ordinarily seem to think it is (Ruse 2001).

If, however, we in this way make "contact" a broader category than Haught seems to think, it is then the confirmation view that becomes one particular version of the contact view. If religion, at least in its theistic interpretation, could provide a general vision of things that consistently nurtures the scientific quest for knowledge and liberates science from association with imprisoning ideologies, then there is contact between the two domains. Thus, what seems to be lacking is a typology that illuminates different versions or sub-models of the contact view.

Stenmark's Typology

Mikael Stenmark's typology is influenced by those developed by Ian Barbour and John Haught, but it attempts to avoid the shortcomings of their typologies. Stenmark takes the idea behind a good typology to be to identify and relate in an unbiased way the key positions within the specific field that the typology in question attempts to illuminate. He proposes a fourfold taxonomy to capture different ways of relating science and religion (irreconcilability, contact, independence, and replacement), which is supplemented by a distinction between different sub-models particularly when it comes to the category of "contact" (Stenmark 2004 and 2005).

A first possibility is to maintain that science and religion are rivals. They compete on the same turf, and in the end, one will emerge as the winner. There is no way in which one can be both properly scientifically minded and a true religious believer. This *irreconcilability view* (or conflict view) has been defended by a philosopher like John Worrall and scientists such as Richard Dawkins and Peter Atkins.

According to the *independence view*, conflicts between science and religion could and should be avoided if they are taken to be inquiries in

separate domains. Its defenders maintain that science and religion are not rivals at all because they have no turf in common. Stephen Jay Gould, for instance, claims that "the net, or magisterium, of science covers the empirical realm... The magisterium of religion extends over questions of ultimate meaning and moral value. These two magisteria do not overlap, nor do they encompass all inquiry" (Gould 1999: 6).

Any view in between the irreconcilability view and the independence view would have to presuppose an overlap between science and religion, that is, some area of contact. Stenmark follows John Haught and call this option the *contact view*. The idea is that the two practices are distinct but their content can influence each other, even to such extent that reformulation or modifications of one or both is necessary. However, not merely conflict or tension (causing reformulation or modifications) is possible in the area of contact but also consonance or even harmony.

A fourth possibility is the *replacement view*. Typically, this view is expressed in terms of science replacing religion. The idea would then be that science today or in the near future could replace religion: that is, the domain of science can be expanded in such a way that science might become our new religion. Perhaps the best-known advocate of this view is the father of sociobiology, Edward O. Wilson.

Stenmark's typology can be summarized in the following way:

1. *The irreconcilability (or conflict) view* is the view that science and religion cannot be reconciled while still maintaining the distinctive features that characterize them as science or as religion and not some other human activity.
2. *The independence view* is the view that science and religion are compatible because they are two completely separate but legitimate practices with no overlap or contact.
3. *The contact view* is the view that science and religion are distinct practices, which nevertheless can come in contact with each other, that is, there is some area of overlap.
4. *The replacement view* is the view that science could today or in the near future replace

religion: that is, the domain of science can be expanded in such a way that science might become our new religion.

Stenmark maintains, however, that when we turn to the specialist literature that deals with science-religion relations, we discover that most of the ideas expressed would presuppose an acceptance of the contact view. That is to say, most of the scholars engaged in the dialogue today maintain or assume that science and religion can be combined or reconciled in some way or other; yet, they differ on how exactly this should be done, developing a variety of different standpoints. The challenge is to provide an impartial and illuminating account of the differences among those who subscribe to the contact view.

What is evident, however, is that some scholars think that the contact between science and religion is fairly limited, whereas others seem to think that it is a substantial contact between the two practices. Stenmark's proposal is therefore that we are making a distinction between *strong* and *weak contact views*. The difficulty is to state that distinction more precisely since scholars locate the contact in very different places (Stenmark 2007: 694–696).

Ian Barbour's theology of nature approach, for instance, entails that the main source of theology lies outside science, but scientific theories may nevertheless affect to some degree the reformulation of certain religious doctrines, particularly the doctrines of creation and human nature (Barbour 1997: 98). Gordon Kaufman argues that changes in scientific theory make it even necessary to reconstruct the core conception of God that has traditionally been endorsed by Christians, Muslims, and Jews (Kaufman 2001: 409–25). Less radical is Arthur Peacocke's position, which attempts to preserve the traditional idea of personal conception of God. Still he suggests that the starting point for theology should be the natural sciences, hence his talk of a "naturalistic theology," and in this respect, he goes beyond the theology of nature approach identified by Barbour (Peacocke 2007: 8 f.). Advocates of natural theology, on the other hand, claims that the contact is positive rather

than negative for traditional religions and more direct since their idea is that the existence of God is made probable by evidence discovered by science such as the "fine-tuned" character of the universe, namely that the fundamental parameters of the early universe seem to be fine-tuned for the conditions required for the emergence of life and intelligence. Creationists and defenders of intelligent design would probably see the contact between science and religion to be even greater but negative not for religion but for science because in certain cases, religious beliefs affect significant reformulation of certain scientific doctrines, such as evolutionary theory.

Although these approaches differ radically, all of them are examples of the contact view. They all agree that science and religion are distinct practices, which can nevertheless meet each other, and in those areas of contact, there could be a relationship of harmony, consonance, tension, or conflict between the two.

Stenmark's suggestion is therefore that we define the *weak contact view* as the view that when the relationship between science and religion is not one of harmony or consonance, merely minor reformulations or changes of religion (and sometimes of science) are called for in the area of contact. The *strong contact view* is the view that when the relationship between science and religion is not one of harmony or consonance, then substantial reformulations of religion (and sometimes of science) are called for in the area of contact.

Although the general assumption of the science-religion debate is undeniably that contemporary science is okay as it is and that it is religion that needs to change; the bracketing in the definitions are meant to be a reminder that some defenders of the contact view deny that the traffic only goes in one direction, from science to religion. In their understanding, science sometimes need to change rather than religion.

Stenmark's typology might therefore be understood to actually be fivefold, containing the following ways of relating science and religion: the irreconcilability (or conflict) view, the replacement view, the strong contact view, the weak contact view, and the independence view.

of KwaZulu-Natal, Pietermaritzburg,
South Africa

This is a foundation concept in African indigenous relational ethics. It refers to a belief among peoples in Africa that humans are made persons because of, and through, other persons. That is, that we are who we are through the support and mentorship of others. In this perspective, progress in our lives is influenced by the operation of the principle of mutuality of obligation and care between the individual and the community.

UFO

► [UFO Cults](#)

UFO Cults

Justin E. Lane
School of Anthropology, St. Peter's College,
University of Oxford, Oxford, UK

Related Terms

[Aliens](#); [Extraterrestrials](#); [Heaven's gate](#); [Räelian movement](#); [Solar temple](#); [UFO](#); [Unarius academy](#)

Description

The terminology “UFO cult” can be misleading in that the groups do not worship UFOs (unidentified flying objects), rather the beings that they believe control or create UFOs. Religions based around beliefs in UFOs and extraterrestrial beings are mostly a product of the past 150 years. Such beliefs are oftentimes similar to those of New Age religious groups, and one could say that UFO cults are a form of New Age

religion (Albanese 2008). Although theological ties between the two are similar, social structures of UFO cults are more discernible.

Emanuel Swedenborg's publication claiming that he communed with spirits from other planets in 1758 (Swedenborg 1758/2006) is accepted as the first claim of communication with ► [extraterrestrials](#), but otherwise the idea lay fairly out of the public eye until the advent of spiritualism in the late nineteenth century (Albanese 2008). After the late 1940s, the idea of the existence of ► [extraterrestrials](#), and possible communication with these beings, became a common notion. Their publicity and popularity helped push the idea into contemporary western culture.

Many groups have a Christian background and use the Bible, supplemented by a number of unorthodox or apocryphal texts, as the basis for their beliefs. As recently as the Cold War, the theologies started to emphasize a transition into a "New Age," where the knowledge of technologically superior ► [extraterrestrials](#) is used to enlighten humanity (Albanese 2008).

Recent developments in UFO cults have been traced by the media, often in a negative light. During the late 1990s, a string of suicides portrayed the entire body of UFO traditions negatively. The deaths of the members of the Solar Temple and Heaven's Gate fueled the media's portrayal of apocalyptic and millennial cults during the coming of the year 2000. Since then, legal battles have come to the forefront of media coverage, the debate usually being whether or not UFO-based religious groups are legitimate religions and therefore eligible for certain tax exemptions (Melton 2000). After the year 2000, the millennial beliefs of many groups have refocused on a "global consciousness shift" placed at the end of the Mayan calendar cycle ending on December 21, 2012.

Self-identification

Science

One could not say that UFO cults, if taken as one body, identify as a science, but there are

some groups that claim to be a science, such as the Unarius Academy. Although these groups rely in part on the existence of other intelligent life in the cosmos, their methods are not always believed, even from within the tradition, to be fully scientific.

Religion

Some, but not all, UFO cults do not identify as a "religion" due to their identity as a "science," in which case religious identification comes secondary to their identity as a science. Some religions blur these identities, such as Scientology, which markets itself as a science or a psychology; however, many legal battles have been fought to legitimize it as a religion (Melton 2000; Cowan & Bromley 2007).

Characteristics

The marker of this tradition is the belief that UFOs and ETs are superhuman agents acting in our world. The novel nature of such beliefs also allows it to be marked as a subset of the more general typology of new religious movements.

Relevance to Science and Religion

Many UFO cults have an interest in the interchange of science and religion to publicly –and empirically– prove or produce circumstantial evidence for the existence of UFOs and ETs. Otherwise, the interest lies mainly in the use of science to back up the religious beliefs a particular group may hold.

Sources of Authority

Authority comes from a variety of sources, unique to each group. Many UFO cults have a paradigmatic alpha leader who leads through teachings and revelations. Some traditions operate via texts and involve mainly audience-type adherence. Similarly, a growing trend involves the dissemination of information through the

Internet for proselytization and teaching. Individual teachers are the most common authority and derive authority from the ability to obtain knowledge. Some leaders claim that they are physically extraterrestrial, they are inhabited by an extraterrestrial spirit, or in communication with ► [extraterrestrials](#), in order to legitimize authority.

Ethical Principles

Ethics mainly reflect humanist principles and global themes. Some scholars posit that the Cold War context that gave rise to most UFO cults, and the global concerns that arose during this time period, informed the global ethical concerns in an age of potential nuclear warfare (Rothstein 2003).

Key Values

Like most aspects of UFO cults, values are unique to individual groups and usually reflect their respective authority. Many themes run through a majority of traditions, such as environmental concerns, disarmament, and human health concerns (especially in relation to nonhumans, i.e., ► [extraterrestrials](#)). Many groups value medicine and health, consistent with the authority granted to scientific research by the group. The values of some groups challenge those of their host societies and cultures. For example, the International Raelian Movement openly endorses public nudity in a society that eschews such displays (Palmer 2004).

Conceptualization

Nature/World

The natural world is often dualistic in that there is a world where humans interact and our physical reality is manifest, but there is also a spiritual world, which exists along side of our own yet is also able to manifest itself into the physical realm.

Human Being

There is no clear boundary between what is or is not human; rather, the main ontological boundary is between terrestrial and extraterrestrial; biological or semantic definitions of human are not significant in relation to the place of origin.

Life and Death

Reinterpretations of the Judeo-Christian creation story are common origin myths, where concepts such as angels are reinterpreted as ► [extraterrestrial](#) beings. Usually, the afterlife is a Judeo-Christian reinterpretation when time after death is spent in the company of extraterrestrial gods in a non-terrestrial paradise. However, reincarnation is also a common belief.

Reality

Reality is treated in much the same way as “nature” or the “world.” The reliance of empirical evidence, either scientific or the reoccurring sightings of UFOs and reports of ► [extraterrestrials](#), leads one to see that UFO religions view “reality” as something tangible; however, reality is not limited to the world around us. UFOs, their abilities, and the ability for a human to contact extraterrestrial entities violate traditional views on reality, but these concepts are very real to a believer.

Knowledge

Knowledge can be anything that is learned, or for some traditions, something unlocked through experience and progression.

Truth

When truth is important to one particular group, it is only important as a concept that represents that which is known to be true and usually understood as subjective.

Perception

Perception is usually similar to beliefs of New Age religions in that it is something perceived by the human mind.

Time

Conceptions of time exist in parallel to notions of reality and nature. For traditions that view the

world linearly, time has a beginning and an end, usually similar to the Judeo-Christian creation myth and apocalyptic end time where the world enters a Utopian age. For some groups, time moves incrementally, where humans progress to the next level of existence or age when adequate spiritual and/or technological advancement is achieved. For other groups, time is cyclical; this is most prominent in traditions that believe in reincarnation.

Consciousness

Consciousness is not generally defined across UFO groups. However, consciousness and debates on its nature, its existence, and its meaning are prominent discourses in the groups individually.

Rationality/Reason

Many traditions place great weight on rational thought, but this will always come second to the value placed on the faith and authority in a UFO cult.

Mystery

Mystery is viewed in relation to revelation and truth, anything that cannot be revealed or shown to be true is a mystery; it is therefore more of a temporary label for something that is not yet known.

Relevant Themes

Important to most groups is the concept of potential. Many groups emphasize what the world or humanity could be like at its pinnacle. Like most eschatological religions, the potential for this paradise to manifest itself in our reality weighs heavily on the traditions, but unlike Christian apocalyptic beliefs, the paradises are often extraterrestrial.

Upper Paleolithic

Matt Rosano

Psychology Department, Southeastern Louisiana University, Hammond, LA, USA

A period of time beginning about 35,000 years before present when increasingly sophisticated stone tools, complex social systems and settlement patterns, cave art, and other abstract, symbolic artifacts emerge in the archeological record in Europe. This period is often cited as a “cultural revolution” marking the beginning of modern thinking. Recent work questions the extent to which modern behavior emerged suddenly with the Upper Paleolithic as increasing evidence of modern behavior continues to accrue in the pre-Upper Paleolithic African archeological record. However, the quantity and, to some degree, quality of UP artifacts associated with modern cognitive abilities (e.g., symbolism) continue to stand as significant.

Urology

Rüdiger Heicappell

Department of Urology, Asklepios Klinikum Uckermark, Schwedt, Germany

Description

Urology focuses on the diagnosis and conservative as well as surgical therapy of diseases of the

urinary system (kidneys, ureters, urinary bladder, urethra) and the male genital tract (testicles, epididymis, seminal vesicles, penis, prostate). Since circumcision and catheterization of the bladder have been verified to date back to very early in medical history, the existence of Urology dates back to ancient Egypt, particularly to time between 2318 and 2300 BC. Urology was part of surgery, and it was not before the end of the nineteenth century that Urology was developing into a specialty of its own.

This development was driven by three major medical inventions:

1. The introduction of antiseptic principles into surgery (Abbou et al.)
2. The introduction of a special instrument to evacuate bladder stone fragments (Bigelow 1875) (Best and Neuhauser 2004)
3. The introduction of endoscopy of the bladder (Maximilian Nitze 1879) (Chaussey et al. 1980)

Urology was established as a science of its own first in France, where in 1890 Felix Guyon was appointed to a chair of “Clinical Urology” in Paris. It was also in France where the first scientific association of urology, the Association Francaise d’Urologie, was founded in 1896.

There are two important recent developments in Urology:

1. The development of the extracorporeal shock wave lithotripsy (ESWL) that was first introduced in Germany as a noninvasive method to treat stones in the kidneys and the ureters and almost completely replaced open surgery (Herr 1764).
2. The development of laparoscopic techniques for surgery of the urinary tract and the male genital organs. These techniques have a major impact on patients comfort in that they reduce pain and shorten the hospital stay (Schuessler et al. 1997). Moreover, laparoscopic techniques are currently improved by the addition of three-dimensional vision and virtual reality. This technique, robotic laparoscopic surgery, initiates a change of paradigms in urologic surgery, since the surgeon works on a remote computer workstation without physical contact to the patient (Smith 1979).

Self-identification

Urology uses scientific methods to gain knowledge and to evaluate clinical experience with new approaches to diagnosis and therapy. The major keys to understanding of urologic disease are pathology and pathophysiology. New therapies or diagnostic methods are evaluated using the scientific methods of medical statistics. By this approach, Urology identifies itself as a science.

Characteristics

Urology is a medical subspecialty not only derived from surgery but also from medicine. Urology deals with the diagnosis and therapy of diseases of the urinary tract in men and women and in the male genital organs. The distinction to other medical specialties is by the focus on particular organs.

Relevance to Science and Religion

Urology sees itself as a part of scientific medicine and thereby contributes to the understanding of human health and disease as a whole.

Sources of Authority

Like in other medical specialties, it were the outstanding contributions of single physicians and researchers that were authoritative in the past. These days, journal articles and congress presentations are the major source for distribution of knowledge in Urology. Since it is virtually impossible to read all relevant journal articles even in a relatively small specialty like Urology, the direct impact of individual journal articles is decreasing. Systematic reviews and clinical guidelines are gaining more and more importance in this context. The major source of authority nowadays is therefore statistical proof of significance.

Ethical Principles

There is no formal written compliance to certain ethical standards in Urology as well as in other medical specialties. However, it can be assumed that all urologists worldwide adhere to the principles of the oath of Hippocrates (460 BC–370 BC) in general and the Declaration of Helsinki as far as clinical studies are concerned.

Key Values

The key values of Urology are the prevention, identification, and treatment of diseases of the urinary tract and the male genital organs.

The major key value is removing the burden of suffering from each individual patient. For this purpose, a variety of minimally or noninvasive methods of diagnosis and therapy have been developed. One key development in diagnosis was the introduction of endoscopy of the bladder (cystoscopy) by Maximilian Nitze (1848–1906) which – for the first time – allowed for nonsurgical inspection of an internal organ and thereby formed the basis of endoscopic surgery. In the 1980s, stone therapy was revolutionized by the introduction of a new noninvasive form of stone therapy (extracorporeal shock wave therapy: ESWL) which almost completely replaced open surgery for stones in the kidneys and the ureter. Nowadays, there is a strong focus on laparoscopic surgery which in some fields is expected to replace open surgery soon.

A second key value of Urology focuses on preservation of organ function. Reconstructive surgery, such as replacement of a tumor-infiltrated bladder by a “neobladder” crafted from ileum, forms a major part of Urology. Moreover, kidney transplantation is part of Urology and helps people to survive without dialysis.

A third key value of Urology is the cooperation with other medical specialties. Urology has a strong interdisciplinary approach to diagnosis and therapy. This applies – among others – to the therapy of urologic cancer and the diagnosis and therapy of neurologic disease of the urinary tract, human reproduction, and venereal diseases.

Conceptualization

Nature/World

Nature is conceptualized as the natural environment which provides the basic resources required for human living.

The world is conceptualized as the place that hosts human beings and all other components of nature.

Human Being

A human being is conceptualized as a complex biological unit with unique potentials. These include (among others) a highly functional brain, emotions, the capacity for abstract reasoning, language, and bipedal walking.

Life and Death

Life is conceptualized as a coordinated function of complex biological systems coordinated by the brain. Male reproduction and urinary excretion are subfunctions of life, the latter of which is essential for survival of a human organism, and the first essential for long-term existence of mankind.

Reality

There is no specific concept of reality in Urology; however, Urology uses surgical methods that are based on “virtual reality,” such as robotic surgery, where the surgeon does not have haptic contact with the patient and performs surgery from a computerized workstation.

Knowledge

Knowledge is the basis of Urology as of all other medical subspecialties. Since medical knowledge is based on personal experience and controlled clinical trials, it is essential to organize knowledge according to commonly accepted rule in order to transfer knowledge between generations of physicians.

Truth

Truth is an essential prerequisite in the development of knowledge. Only trusted sources are generally accepted in this specialty, like all others in medicine.

Perception

Perception is conceptualized in Urology as the ability of the physician to “see, what is there.” However, perception is not restricted to sight but also includes hearing, touch, and smell. The sense of taste is currently not used any more in Urology.

Time

Time may be useful in Urology for diagnosis in difficult situations. If a CT scan reveals some minor changes in a certain organ, repeating the examination after some time can help to make the correct diagnosis. For example, if after 6 months a minor change in an organ has not further grown, it should be unlikely that the diagnosis is “cancer.”

Consciousness

There is no specific concept of consciousness in Urology. However, the loss of consciousness under general anesthesia was an important prerequisite for making major surgical operations possible. In addition, loss of consciousness may be an indication of severe urologic disease, such as kidney dysfunction or blood loss after internal organ injury.

Rationality/Reason

Rationality and reason form the basis for decision making in Urology.

Mystery

There is currently no concept of mystery in Urology, since Urology is based on scientific concepts rather than mystery.

Relevant Themes

Science dominates two aspects of Urology:

1. The active development of this medical specialty is critically based on scientific research. Research, however, is generally restricted to specialized institutions, such as universities, university hospitals, and research centers.
2. Daily practice of Urology is dependent on science, since its methods are based on science. Outside research institution, the major focus of Urology is on patient care rather than on the active development of science.

Description

Utilitarianism is a moral theory or ethical perspective which judges the morality of actions based on an evaluation of consequences (or effects, outcomes). The good consequences of actions (e.g., that people's preferences are fulfilled, or that they become happier) are

weighed against the bad consequences (e.g., any pain or suffering which the action leads to), and the central ethical obligation is to perform the action whose overall consequences are the best (or most beneficial) in a given situation. By implication, actions are considered morally wrong if there was something else which the agent could have done in the situation which would have produced a better outcome. Being a central form of teleological or consequentialist ethics, utilitarianism is commonly contrasted with deontological ethics – which judges the morality of actions based on their adherence to (most often strict) action-principles or rules – and virtue ethics – which holds that morality essentially concerns the development of virtuous character traits. Consequently, utilitarianism holds that whether a certain action is right or wrong does not depend on what kind of action it is (whether, e.g., it is a case of lying or killing) or with what intention it is performed (whether, e.g., it is performed with good or bad intentions). Rather, the central issue is what consequences or outcomes different actions produce, that is, what the results of different actions are.

Utilitarianism was first introduced by the British philosophers Jeremy Bentham and John Stuart Mill in the late eighteenth and early nineteenth centuries. They were both political thinkers and used their account of utilitarianism primarily to justify certain legal and social reforms, which were generally considered radical at the time. Interestingly, one of Bentham's and Mill's main ideas was that utilitarianism should be the ethical theory of choice for people in a post-religious and scientific society, since it essentially poses a challenge to all those philosophers and theologians promulgating, for example, a sacred right to life or a list of the "natural rights of men." Before we are to believe in such things, Bentham and Mill suggested, we must be presented with some idea as to how they connect with what people actually value – that is, with people's welfare. However, it may be noted that some utilitarians argue that the theory also fits very well with many religious conceptions of morality. Indeed some argue, for example, that utilitarianism is the most plausible interpretation of the "Golden Rule"

common to several religious traditions (roughly that you must “only treat others in a way in which you would like to be treated yourself”). According to utilitarianism, namely, what ultimately matters is how people are affected (roughly how well-off they are made) by different actions – and all people’s welfare matters equally in this, that is, I cannot count my own welfare as more important than yours when evaluating the consequences of actions.

What is roughly utilitarian moral thinking is often involved in contemporary debates on more particular ethical issues – like, for example, charity, abortion, and euthanasia. Utilitarianism is probably the best explanation of the popular view that we have strong moral reasons to give to charity, for instance, since – as was just noted – everyone’s welfare is given equal moral weight in this perspective. Thus, even though I may desperately want an iPod for myself, I would probably make the world a much better place if I gave the money away to famine relief. Arguments to the effect that abortion or euthanasia should be legal because of the negative effects associated with prohibitions are also rather straightforwardly utilitarian; that is, they are arguments about what sort of policy would produce the best outcome. At the same time, it may be noted, there can be utilitarian arguments going in the opposite direction as well. There may, for instance, be utilitarian grounds for arguing that numerous individual instances of abortion or euthanasia are immoral – because it probably would have had better effects in many situations to let the child or elderly person live. In the end, however, it is often rather difficult to say exactly what utilitarianism implies in a given situation, and this is so for several reasons. One reason is that one never can know in advance what consequences a given action will have (more on this below). Another reason is that several strands of utilitarian thinking may be possible.

While utilitarianism to some extent is a more uniform moral tradition than, for example, deontological ethics, a number of variations of its central theme are indeed possible. A first dimension of variation is what more precise theory of value one relies on, that is, exactly what it is that

makes outcomes good or bad. Many utilitarians use the general term “utility” (from which the theory derives its name) to denote whatever it is that is valuable in life or society. But it may be noted that many different views obviously are possible on exactly what utility is. Bentham’s and Mill’s classical view on this was that only happiness or pleasure matters (this is commonly called Hedonism, or Hedonistic Utilitarianism). What this means, it should be added, is that only pleasure is *intrinsically* good (and that only pain is intrinsically bad). Many things can be *instrumentally* good in the sense that they *lead* to happiness. So, for instance, knowledge and virtue can be instrumentally good in so far as they tend to lead to happiness, both for the one who attains them and for people around them. But knowledge and virtue would not be good, or so the idea goes, if they did not have these relations to pleasure and pain. According to classical utilitarianism, then, the only thing which is good *in itself* is pleasure. But this is not the only possible view. According to another view (called Preferentialism), knowledge and virtue are only valuable to the extent that they lead to people getting what they want – that is, to the *satisfaction of preferences*. A good deal of utilitarian thinkers have supported this view, but some support yet another view (sometimes called Objective List Theory, or Perfectionism) according to which such things as knowledge and virtue indeed can be good *in themselves* and not only instrumentally good.

A second dimension of variation is perhaps more technical and concerns value aggregations, that is, how individual instances of whatever is good or bad are aggregated into one overall measure. Bentham’s and Mill’s credo is often restated as “the greatest good for the greatest number of people.” However, we may note a certain ambiguity in this credo: In certain situations, one’s only options may be to either give a greater benefit to fewer people, or to give a smaller benefit to more people. That is, one may have to choose between the greatest good, on the one hand, and the greatest number of people, on the other. What should one choose? The classical utilitarian answer to this question is that one should try to find the best mix between

the two, that is, that it is the *total amount* of utility which matters (this is sometimes called Total Utilitarianism). In the case just mentioned, the total amount of utility is most easily calculated by taking the size of the benefits distributed and multiplying this by the number of people who get it. If the number of people to which you can give the smaller benefit is sufficiently large, then, this may outweigh the fact that the benefit is smaller and you should then go for the smaller benefit. By caring about the total amount of utility, classical utilitarians suggest that they strike a reasonable balance between the quality of benefits and the quantity of people enjoying them. But, once again, this is not the only possible view. According to a different view (called Average Utilitarianism), “quality is more important than quantity” and so what ultimately determines whether an action is right or wrong is how the *average* level of welfare in the world is affected.

A third and final dimension of variation is exactly how one goes from an evaluation of outcomes to the moral evaluation of actions. The underlying goal of utilitarianism is roughly to steer our behavior in the direction of producing the best outcomes. Now, classical utilitarians take this to rather straightforwardly imply a criterion of rightness for actions; as noted above, the central ethical obligation is said to be to perform the action whose overall consequences are the best in the situation. (Just to clarify: What determines the rightness of a particular action are not only the consequences of that distinct action, it may be noted, but also what the consequences would be of all other actions open to the agent in the situation. In most situations in our lives, utilitarianism suggests, there are simply more than one line of action “open” to us, that is, there are a lot of things that we could do if we wanted to. The morally correct action is then the *one out of these* which produces the best consequences.) But this is not the only possible view. According to so-called Rule Utilitarianism, one should instead perform actions which are in line with the *set of rules* which produce the best consequences – that is, one must first figure out what set of rules that would have the best outcome if everyone

followed them, and then one’s ethical obligation is to abide by this set of rules. Rule Utilitarianism may be seen as a sort of mix between utilitarianism and deontological ethics.

According to proponents of utilitarianism, this sort of moral perspective has a number of characteristics which should make it more appealing than rival ethical theories (e.g., deontological ethics or virtue ethics). As noted above, utilitarian ethics is sometimes said to be in line with the Golden Rule, for instance, and also to provide a kind of secular test of, or standpoint against which to counter, appeals to supposedly “fundamental values” (like dignity, liberty, or equality) which not everyone share. Most importantly, however, utilitarian ethics is typically held out to be a very simple ethical theory: All that matters is utility, or people’s happiness, and actions are simply morally right or wrong in so far as they maximize this kind of value. Of course, on the other hand, critics of utilitarianism suggest that its simplicity is one of its main weaknesses. And indeed, it may be noted that a good deal of philosophers and theologians have been very critical of utilitarian ethics. The central criticisms of utilitarianism can be divided into two main groups: One the one hand, it is often argued that utilitarianism is too *permissive*, and on the other, it is sometimes argued that utilitarianism is too *demanding*.

The argument that utilitarianism is too permissive takes as its starting point the fact that utilitarianism can approve of all kinds of actions, however barbarian or morally repulsive they may seem to be, as long as they happen to maximize utility. As noted at the outset, utilitarianism holds that whether a certain action is right or wrong does not depend on what kind of action it is (whether, e.g., it is a case of lying or killing) or with what intention it is performed (whether, e.g., it is performed with good or bad intentions) but the only interesting issue is what outcomes different actions produce. Here are some things which utilitarianism often is thought to be unable to accommodate for: Firstly, the idea that human beings have certain fundamental *moral rights* does not easily square with the theory. Utilitarians may respect such rights when nothing can be gained by contravening them, but as soon

as one can increase the general welfare level in the world by contravening such rights, this is morally required. Secondly, the fact that someone has promised me to do X is never directly or in itself a reason for their doing X. Since utilitarianism only cares about consequences or, one may say, *forward-looking* considerations, *backward-looking* considerations like the fact that someone has promised something are never morally relevant as such.

Thirdly, utilitarianism is sometimes said to be at odds with our most basic judgments about *distributive justice*. Say that I can confiscate all of the resources of one person and distribute them to enough other people so that the total sum of preference satisfaction is greater than before. If this is possible, utilitarianism suggests that I ought to do so (and, indeed, that it would be wrong not to do it). I may even have an obligation to do so if the first person dies as a result of my behavior, and the people to which I donate the resources were quite well-off to start with. Fourthly, utilitarianism seems to be inconsistent with popular judgments about *retributive justice* as well. While it most often may be best to punish the guilty for felonies, there is nothing in principle which prevents utilitarians from accepting punishment of the innocent. In fact, utilitarianism seems to imply that convicting an innocent person to death may be justified as long as it prevents enough other people from committing serious crimes.

Apart from being criticized for being too permissive, utilitarianism is sometimes also criticized for being too demanding. If there is one thing which utilitarianism is quite insistent on, namely, it is that we ought to dedicate our entire lives to increasing the general level of welfare in the world. But what this means, critics say, is that we are required to give up all of the life projects we currently are engaged in and completely dedicate ourselves to the serving of others. Some critics suggest that this in a sense means giving up our very *identity*, since we to a large degree tend to identify ourselves with our personal projects. According to others, what is most problematic in this context is that utilitarian ethics is at odds with the value of personal relationships. At the core of

utilitarianism, as noted above, lies the idea that we should pay equal attention to how everyone's welfare is affected by our actions. However what this means in practice, it is argued, is that I must care just as much about, for example, other people's spouses as my own, and as much about other people's friends as my own. It is not difficult to see why this result has been thought to be deeply troubling.

One could say that philosophers defending utilitarianism, in turn, generally have presented three main kinds of responses to the criticisms above: First of all, many utilitarians suggest that their theory actually is much closer to some of its rivals than what is generally appreciated. Even though the theory *in principle* implies that even quite abhorrent actions could be justified if and when they maximize utility, such actions will quite rarely be the best alternative *in the real world*, they say. Convicting innocent people to death will seldom lead to much good consequences, for instance, because the fact that they are innocent will most often come out in the end. And redistributing wealth from the poor to the rich will certainly never be a good thing, because the poor simply get more enjoyment out of a given amount of resources than the already well-off do. In essence, then, the differences between utilitarianism and rival ethical theories may often be exaggerated.

Secondly, many utilitarians actually suggest that their theory is consistent with the use of non-utilitarian moral principles as a method for decision making. As noted above, there are many reasons for why it seems almost impossible to *know* what action utilitarianism favors in any given situation, and so what actions ultimately are morally right and wrong. Consequences are by definition things that happen in the future, and only seldom will we know for certain what even the most immediate and local outcome of a specific action will be. But, of course, utilitarianism does not only care about the *immediate* consequences of an action, but everything which happens as a result of this action until the end of time. Nor does it only care about *local* outcomes, but how the world (or universe) *as a whole* is affected by a certain action. Since it is impossible to know exactly what action

maximizes utility in real life scenarios, many utilitarians suggest that various kinds of rules of thumb may be used. And these rules of thumb may indeed be exactly the kind of principles which the critics insist on; that is, roughly, that no horrific actions are to be performed. Since the situations in which the action which maximizes happiness will be an instance of, say, violating people's human rights or breaking one's promises are likely to be uncommon, namely, it may be better to never even consider such actions as viable alternatives than to do so and sometimes break one's promises when it has disastrous consequences.

The introduction of rules of thumb into utilitarian thinking is interesting. An obvious observation is that these rules seem quite different from the core idea of utilitarianism, and so there seems to be some tension between going for maximizing utility and abiding by these rules of thumb. But the general idea here is simply that, when one does not know what specific *action* that maximizes utility, a reasonable thing to do may be to adopt the *decision procedure* which, if one follows it over a longer period of time, has the best consequences compared to (ones' following) other decision procedures. In this sense, then, utilitarians suggest that they can provide utilitarian reasons for following seemingly non-utilitarian moral principles. Indeed, as noted above, utilitarians typically commend themselves exactly for being able to say so much about ethics from such a simple thing as an appeal to utility.

Bringing in rules of thumb may work in some situations, but it may not work in others. If or when all of the above fails, utilitarians typically resort to a third and final way of responding to the criticisms outlined before; namely to fully *embracing* the supposedly absurd implications of their theory. Most of the criticisms above are based on our intuitive judgments, it may be noted. Critics say that it just seems so *counterintuitive* to us to say that convicting innocent people sometimes may be morally right, or that we ought to dedicate our whole lives to the serving of others. But some utilitarians respond to this by saying

that the fault simply may lie in our intuitive judgments, or perhaps our moral upbringing, more than it lies in utilitarianism. For instance, the reason for why we think that killing always must be morally wrong may just be squeamishness on our part – that is, that we hesitate to do the right thing when it calls for actions which we find unpleasant for some reason. Similarly, perhaps our aversion against dedicating our whole lives to serving others may be self-indulgence. Instead of modifying utilitarianism to suit our own intuitive judgments, then, perhaps we must simply modify our judgments. On this perspective, it should be noted, utilitarianism is indeed a radically revisionist ethical project.

The considerations above suggest that utilitarian ethics, although perhaps theoretically simple, is an enormously flexible moral framework. And perhaps it is this flexibility which explains utilitarianism's longstanding place as one of the main contenders in moral philosophy. Whether utilitarians ultimately are able to avoid all of the problems which their theory is said to have, however, and whether utilitarian ethics indeed captures something important in our ethical thinking, will probably be central issues in debates for centuries to come.

[Abuse](#); [Aggression](#); [Hostility](#)

Description

Violence is the use of physical or verbal force or exploitation against self, others, or property whose effect is bodily or psychological harm. As a human action of hostility and aggression, violence needs to be distinguished from other events, including natural disasters or accidents, that might also cause injury, damage, trauma, loss of life, or property, but whose cause is ontic or physical evil.

Violence is an act that goes against human dignity and reason, and from a religious perspective, even against divine law. However, the interpretation of actions as reasonable or otherwise – and consequently as morally good, evil, or neutral – is, to some extent, culturally and historically conditioned. At different points in history, and in different cultural contexts, actions that today would indisputably be considered to be violent and immoral were tolerated and even normative, for example, slavery.

The ambiguity of violence lies in the fact that the same act, for instance, physical harm, can be of willful cruelty and therefore sadistic, a measure of self- or communal defense interpreted as heroic, a method of social control, indoctrination, and discipline for the greater good of societal concord, or even a combination of the above. For this reason, we need to distinguish between necessary, or at least tolerable or proportionate human acts of violence, and willful violence that is totally unnecessary. While irrespective of the context, and insofar as it leads to perceptible harm, all violence is a lesser good, and therefore an evil, moral culpability for the act still needs to be discerned through the intent of the actor, even if it is legitimate to argue that unnecessary violence is intrinsically evil. For this reason, violent acts like war, capital punishment of criminals, extreme disciplinary measures in the education of children or for religious purposes, or even institutionalized violence for public entertainment and spectacle have all been used and legitimized as proportionate actions amid the outcry of others that they are intrinsically wrong.

Moreover, modernity's shift to the rights of the individual, as well as the liberal emphasis on the equality of all citizens rather than a hierarchical organization of society, has alerted us more to the indignity of many violent acts that were previously condoned, for example, war crimes, torture, child abuse, and domestic violence. This shifts the moral locus of violence from the intentionality of the aggressor – which, in any case, can never be fully known – to the effect of the act as interpreted by the victim, other involved individuals, and ultimately, the objective body of the law. Consequently, even when the actual or stated intent of the abuser is morally neutral (for example, burst of

uncontrollable emotion), or even good (for example, the use of force for discipline or law enforcement), a modern emphasis on the individual's rights is less likely to tolerate it. For this reason, in modern western culture, violence is usually associated with acts that go against the dignity of the person, in particular as articulated in the Universal Declaration of Human Rights, and which disrupt social order. The law acts as an interpreter of grievances and injustice and as an arbiter among the rights of the individuals concerned and the general well-being of society. In addition, democracy and public opinion keep in check the possible excesses of law enforcement, in particular when disciplinary measures become violent.

Simultaneously, precisely because violence is socially disruptive, the understanding of its root causes has been a major concern of religious and scientific discourse. It is also a central conundrum for the social sciences and the humanities, whose insights have influenced the positions of scientists and theologians. Most fundamentally, the question of the causes of violence has been approached with a prior philosophical bias of whether human action and, even more pointedly, human beings are inherently free agents or determined automatons, irrespective of whether the “programming” is existential, biological, or social. While most thinkers would not exclude the validity of either side of the freedom-determinism anthropological debate, many religious and scientific approaches can be interpreted as leaning toward one side more than the other.

Major global religions, with their emphasis on moral and spiritual formation, often emphasize the power of the will to control “impulses,” implying that while in the “natural” or developmentally premature state, humans are prone to irrational acts – including violence – based on instinct, emotion, or a combination of both; self-discipline can be inculcated and learnt to control negative inclinations for a more rational, harmonious, or enlightened existence. Simultaneously, the religions postulate the reality of a metaphysical disorder (variously defined) that influences human behavior and relationality.

A central tenet of Christianity, for instance, is the reality of sin as fundamental disorder in the

human relationship with God that corrupts the initial divinely established order of creation, and human relationality. Thus, by virtue of original sin, evil is introduced into the created realm both in its ontic and moral dimensions, just as by the ongoing disobedience of human beings, sinful structures continue to be perpetuated in society and in all human relationships. Still, Catholic and Orthodox perspectives tend to emphasize the inherent goodness that continues to permeate human nature and the created realm even after the Fall, and consequently stress both divine intervention and human free collaboration for the healing of persons and societies in the here and now. In contrast, Protestant views tend to be more pessimistic about human nature, highlighting the corrupting influence of sin in contrast to the weakness of human will, and consequently the absolute dependence on divine intervention for human other-worldly salvation. However, irrespective of the theological nuances in the view of sin, Christianity understands violence as an unbecoming behavior that needs to be controlled, but that can never be completely suppressed until the end times.

In contrast to these classic religious perspectives that promote rules of moral conduct, emphasize the human responsibility to act righteously, and have influenced the modern secular moral imperative of civil society, in these past decades, science has been studying biological causes of violence, that measure an individual's susceptibility to violent behavior, and consequently tend to be more deterministic by virtue of their reductionist methodology. Neuroscientists, psychiatrists, and geneticists are trying to establish the psychophysiology, neurobiology, and psychiatric genetics of aggression, in particular of impulsive violence that undermines the human capacity to act rationally or intentionally. These genetic markers, dysfunctions in neural circuitry, and chemical imbalances in the brain interpret violent behavior as a disease to be prevented as well as cured, but for which the person strictly speaking cannot be held accountable since their freedom is impaired. Less deterministically, the study of the biological basis of violent behavior from an evolutionary perspective suggests that

humans are hard-wired for violence, which would appear to increase the chances of survival in a context of harsh struggle and competition. However, equally likely are postulates that suggest a propensity for collaboration since partnership and cooperation also offer obvious advantages for the propagation of the species.

While useful to our understanding of violence, the relationship between nature and nurture is complex, and these approaches cannot account for all the variables that emerge in actual living in an environmental and social context that shapes our bodies, attitudes, and behaviors as much as they shape it. However, while the environment and social dimension of human development cannot be ignored or separated from nature, psychological perspectives like behaviorism and social learning theory can also be deterministic. From these perspectives, violence is a learned behavior, which can be unlearned with difficulty, appropriated first and foremost in the home – particularly if domestic abuse is present – but also through other “models” that permeate contemporary culture. Violence on television and video games, for instance, has been implicated repeatedly in the development of more aggressive tendencies in children and adolescents.

The notion that violence, or any other behavior, is appropriated through imitation is not new. In fact it is the foundation of most pedagogical models, particularly in antiquity. However, of particular interest is the mimetic theory developed by René Girard, which implicates religion or the sacred in the human propensity to violence that in itself creates the distinctly human milieu of culture. Girard postulates that through imitation, human beings learn to desire the qualities and objects that others already have, a situation that inevitably leads to rivalry and, if it escalates, to violence. Yet when violence in a social context escalates to such an extent that it threatens the integrity of the group, an outsider, or insider with random but distinct features, is marked as a scapegoat for the group's wrath. The scapegoat is murdered, and as the act of violence reestablishes communal “peace,” the victim is hailed as savior and effectively sacralized.

The sacred is thus imbued with violence, just as it serves to control it – to the extent that human history becomes caught up in a vicious circle of violence and scapegoating. Similar to the Freudian emphasis on the unconscious and deep-seated primal rootedness in murder and violence that effectively constructs civilization, Girard's theory postulates how human culture is in itself the milieu of inescapable violence, but also its hope for controlling it.

In conclusion, it is the combination of insights into human violence – from the religious, to the scientific, to the psycho-cultural and learning theories – that can help shed light on some of the most serious expressions of violence in contemporary culture: the rise in terrorism especially in relation to religious fundamentalism; weapons of mass destruction that threaten to wipe out the planet; gang activity in many cities; bullying in schools; domestic violence and abuse; self-inflicted violence through psychological conditions like depression, drug abuse, or eating disorders; the structural violence of economic and political systems that create greater poverty and injustice; violence to the earth that threatens the well-being of the ecosystem.

Vipassanā

Ven. Agganyani

German Vinaya Sangha Association (DBO) and
Centre for Buddhist Studies (CBS), Myanmar,
Bruckmuehl, Germany

Vipassanā (Pāli) or *vipaśyanā* (Sanskrit) means insight, clear seeing. It is a type of meditation (*bhāvanā*) unique to Buddhism. Generally, two types of meditation can be differentiated in the teaching of the Buddha: concentration meditation (*samatha-bhāvanā*) and insight meditation (*vipassanā-bhāvanā*).

In *samatha*, concentration (*samādhi*) is favored and the leading factor. Its aim is to deeply concentrate and calm down the mind by temporarily removing the mental hindrances, which leads to tranquillity, relaxation, and mental peace. The highest state to achieve are the various meditative absorptions (*jhāna*), fine material or immaterial, or even supernormal power or knowledge (*abhiññā*). In contrast, in *vipassanā*, wisdom (*paññā*) is favored and the leading factor. Its aim is nothing less than the irreversible cessation of suffering (*dukkha*), permanent liberation, and full enlightenment, the attainment of *Nibbāna*.

Passanā is seeing or in a figurative sense experiencing or knowing. The prefix *vi* means special, differently, in other ways. Therefore, *vipassanā* is seeing an object differently than normal. Normally we see or understand things wrongly, as concepts and see just the surface. But concepts are the objects for *samatha* meditation only. With *vipassanā*, we penetrate into the real nature of whatever we observe and see or, rather, understand things as they really are. *Vipassanā* needs a great deal of mindfulness (*sati*) to sharpen the mind and to be in the present moment directly

with the respective experience. The object of *vipassanā* is always an ultimate reality (*paramattha-dhamma*), either physical or mental, never a concept (*paññatti*). Ultimate realities are phenomena which can be experienced directly and intuitively with our six senses (including the mind as sixth sense that perceives mental objects like memories, ideas, thoughts, etc.). In *vipassanā*, we penetrate and know their individual characteristics that are typical for them, obvious and unambiguous, and by which one can differentiate and recognize them. This is in order to grasp one phenomenon clearly. The next step to insight is to penetrate to the universal characteristics of the object of ultimate reality, which means the nature that is common to all ultimate realities. These are impermanence (*anicca*), suffering or insufficiency (*dukkha*), and non-self (*anatta*).

A necessary foundation for *Vipassanā* is first the purification of morality (*sīla-visuddhi*), and second, the purification of mind (*citta-visuddhi*) through concentration. Only then the training of wisdom (*paññā*) or insight (*vipassanā*) can start. The practice of *vipassanā* is best described in the Buddha's discourse called "Mahāsatipaṭṭhāna Sutta" (Collection of Longer Discourses, Dīghanikāya, D 22, and Middle Length Discourses, Majjhimanikāya, M 10) and its commentaries. There, four foundations of mindfulness are taught and the respective contemplations, literally "repeated seeing" (*anupassanā*):

1. Contemplation of the body (*kāya*) or rather physical phenomena (*rūpa*)
2. Contemplation of feeling (*vedanā*)
3. Contemplation of the mind or consciousness (*citta*)
4. Contemplation of the *dhammā*, mental objects which are other ultimate phenomena not yet mentioned

In each of the four sections, a variety of exercises is given. Like a refrain, it is always repeated, how and for what purpose to contemplate: "...with effort (*ātāpi*), clear comprehension (*sampajañña*), and mindful (*satima*) – overcoming attachment (*abhiññā*) and grief (*domanassa*) to the world," and "seeing the arising conditions, seeing the dissolving conditions, and both," "internally, externally, and both."

Before meditation really turns toward *vipassanā*, two preliminary insights are necessary:

1. Differentiation between mind (*nāma*) and matter (*rūpa*)

2. Discerning the conditions (*paccaya*) of their arising and ceasing

Following that insight, the characteristics of *anicca*, *dukkha*, *anatta* become apparent and have to be contemplated. Nine steps of insight knowledge follow (See, Path of Purity (Visuddhimagga), Path of Discrimination (Paṭisambhidamagga), Abhidhammattha Sangaha, explanations of meditation masters like Mahāsi Sayadaw (who counts 14), and others), leading through various experiences to disenchantment and equanimity. According to individual personality, one of the three characteristics becomes more significant and clear and should be contemplated intensively as *aniccānupassanā*, *dukkhānupassanā*, or *anattānupassanā*, respectively. When *Nibbāna* is experienced, it consequently will show up with the marks of being signless (*animitta*), desireless (*appaṇihitā*), or empty (*suññatā*). Accordingly, different kinds of emancipation (*vimokkha*) and liberation are taught.

Through slight differences in their appearance, altogether 18 types of contemplations are taught as "great insights (*mahā-vipassanā*)" in Paṭisambhidāmagga and Visuddhimagga.

Virtual Particles

Russell Stannard
Department of Physics and Astronomy,
Open University, Milton Keynes, UK

Because of Heisenberg's uncertainty principle, one can have small fluctuations in energy for short periods of time. This means that subatomic particles can fleetingly pop into existence out of empty space, the energy required to do this being "borrowed" thanks to this fundamental uncertainty. Such particles disappear again so quickly one cannot see them. For this reason they are called virtual particles.

Virtue

Olli-Pekka Vainio
University of Helsinki, Helsinki, Finland

Description

Virtue usually refers to some kind of dispositional perfection or excellence, as its opposite *vice* refers to the lack, or in some cases the excess, of some valued qualities. The central property of virtue is that it is a golden mean between excess and deficit. In many cases, however, the golden mean cannot be defined invariably. For example, what is courageous for one person can be foolhardiness for another. In Western tradition, the fundamental virtue that is supposed to control the reflection and help to find the proper way of conduct is called prudence or practical wisdom (*phronesis*). It is possible that virtues can contradict each other, and practical wisdom is needed to resolve these issues.

Both virtues and vices equip their holders with a potency to act toward some determined end. In classical Christian theology, virtues have been understood as “good operative habits,” which are in accord with reason and our nature. From the viewpoint of actions, being virtuous means not necessarily always succeeding to produce desired ends and simply “being good” (while this is always hoped for), but rather “being for the good” through loving, respecting, protecting, and acting to promote, wishing for, and speaking in favor of good things (Adams 2006).

Some virtues are virtues absolutely while others are so only in a restricted sense, which

means that possession of such a virtue does not make the person good even if the person’s actions may display excellence. For example, it is possible for a criminal to be loyal and courageous but the criminal is not good in absolute sense because he lacks the more fundamental virtues of justice and ► [love](#). Some virtues, such as benevolence, are motivating: they aim a person’s actions toward good ends and thus enable the flourishing of one’s neighbors as well. Some virtues, such as courage and temperance, are structural and they are not defined in relation to some external good or aim. Instead, they are ideal ways of conducting one’s actions.

Virtues and Religions

As virtues, in minimal sense, deal with the excellence of human conduct, they are not restricted within a religious sphere alone. Ancient Greek and Roman philosophers, such as Aristotle, Plato, Seneca, and Cicero, offered accounts on virtues, which were later discussed by religious thinkers. The Roman culture and philosophy was known of its interest in virtues; the concept itself originated from Latin word *vir* (man) and the meaning of virtue was initially associated with manliness. Later the meaning was expanded to include general good behavior, not only in the battlefield but in the everyday life as well. The first Christian philosophers saw in virtue theories something they could resonate with and they were to some extent redefined and absorbed as a part of Christian theology. Sometimes, the pagan virtues were referred as “excellent vices,” that is, good in themselves, but not worthy of Heaven. For example, Thomas Aquinas makes a distinction between acquired and infused virtues. It is possible for anyone to have acquired virtues through their natural powers, but infused virtues are given by God as a gift. The difference between these two classes is that one can lose infused virtue through one action (i.e., mortal sin), but still retain the similar acquired virtues. Consequently, it is possible for one to have all acquired virtues, but still be in the state of sin.

Christian theology divides virtues to intellectual (e.g., science, understanding, art), moral

(e.g., prudence, justice, temperance, courage), and theological classes (faith, hope, charity), although insisting that it is not always possible to draw a sharp distinction between them. In some cases, intellectual lapses are due to moral lapses, and vice versa. Yet, it is possible that persons have differing sets of virtues and very few have them all. One may be courageous, but lack temperance. The virtues are connected through prudence since it is not possible to be wise without being moral, and moral person is necessarily wise.

By and large, all religions and cultures have more or less similar virtue vocabulary consisting of six main classes of courage, justice, humanity, temperance, transcendence, and wisdom, which can be then divided to various subclasses (Peterson and Seligman 2004). Different religions however stress some virtues more than the others, which give the religions some of their special features. Some religious virtue theories are dependent at least to some extent from metaphysical views. In Thomism, *phronesis* presupposes the knowledge of the final causes, that is, God. In Confucianism, the virtuous actions of humans should reflect the balance of *Tian* ("Heaven"). The central virtue in Islam is obedience or submission to Allah from where all other virtues follow.

Even if the form of the virtues can be gained easily by divine act of grace, as it is claimed in Christianity, almost all traditions agree that putting virtues into practice consistently in daily life is hard, and religions contain theorization that seems to denigrate the feasibility of virtuous life. For example, Confucius says: "I have never seen one who loves virtue as much as he loves sex" (Analects 9:17), and in protestant Reformation Aristotelian theories, according to which one becomes good by doing good, were criticized for distorting the doctrine of justification by faith alone. The theologies based on Reformation thought usually held a grimmer picture of human nature than the one that was available for Eastern or Catholic Churches.

Despite these metaphysical underpinnings, it has been suggested that because the virtue

vocabulary is so common to all cultures, the virtue language could function as a common feature that can join together different worldviews at least to some extent and help communities to communicate their values in understandable manner even when there is no consensus, for example, on deontological rules of action.

Virtue Ethics and Virtue Epistemology

The twentieth century philosophy saw the rise of interest in virtues in two related areas: first virtue ► [ethics](#) and then virtue ► [epistemology](#). Elizabeth Anscombe's famous essay "Modern moral philosophy" (1958) criticized the current trends in moral philosophy by pointing out that they speak about laws, but without the notion of the lawgiver. To avoid inconsistencies the post-metaphysical age could benefit from the ancient virtue theories. More specifically, modern virtue ethics grew out of dissatisfaction with deontology and ► [utilitarianism](#), especially in their inability to address classical themes of interest in moral theory, such as inception of moral character and virtuous behavior, wisdom, and moral discernment as personal skills; the role of emotions in habituation; and mundane questions like "what sort of person should I be." Instead of relying on formal guidelines, like Kantian imperative, or the calculation of profit, virtue ethics guides action by trying to conform one's actions according to ideal, virtuous agent (*phronimos*).

Similarly, in virtue epistemology, justified belief is something that conscientious epistemic agent would believe. Instead of concentrating on the features of beliefs (such as whether it is adequately based on evidence) in order to see whether they are justified or not, the focal point now is the enquirer of knowledge and his or her intellectual properties. These virtue-based approaches thus require more holistic understanding of the strengths and weaknesses of human nature than the previous theories (Roberts and Wood 2007). The sciences that are most relevant for virtue theorization are sciences that study human nature and behavior, such as cognitive psychology and neurosciences.

Virtues and Psychology

Virtues are closely linked with character traits and personality. A character trait is a deep-seated disposition to act in certain ways for appropriate reasons. Traits persist over time and are relatively stable. Human personality is formed during the first 20 or so years, and it is very resistant to change, while traits are more fluid. It is possible that two persons have different personalities (say, A has temperance, while B does not) but they may share similar moral character, which is manifested in the willingness of B to apologize whenever she has lost her temper.

From the evolutionary perspective, our psychological mechanisms that control our moral reasoning have coevolved with cultural institutions and practices that give shape to our moral convictions. The basic moral modules are thus to a great extent innate. Jonathan Haidt (2012) has argued that moral reasoning and behavior is linked to various intuitive cognitive modules that vary from person to person, which consequently produce different moral outlooks. Human moral deliberation centers around six basic modules, which are avoidance of harm, fairness, liberty, loyalty, authority, and sanctity. More liberal individuals usually use only the first two modules while conservatives employ all six of them. This often creates puzzling confrontations when the basic moral sentiments and the interpretation of the virtues seem to clash. A spontaneous conclusion here is that the other group is not acting morally and virtuously. Still, the conservative outlook, for example, helps people to cultivate communities that consequently help their members to improve their characters efficiently. It is natural for us to emphasize intra-group fairness because this tends to strengthen our chances of survival. The same applies to empathy and care, which resonates with our attachment system. Our moral modules also work on communal level. Loyalty, self-sacrifice, subordination, respect for authority, and sanctity enhance group cohesion, demarcate the boundaries of the communities, and suppress selfish behavior. Innateness means that these dispositions are easy to learn and compelling, and we are born with tendencies to favor certain

modules over others. These moral foundations can be developed to actual virtues through practice and repetition. Despite the innateness, personal histories and life narratives, and even education and indoctrination, can shape our moral outlook.

Since the twentieth century renaissance, one criticism of virtue theories has been the purported impracticability of these theories. Among others, philosopher Gilbert Harman has criticized the resurgence of virtue-based approaches to ethics, politics, and epistemology. Harman argues that human behavior is best explained by situational factors rather than character traits, and focusing on the personal disposition is counterproductive and misleading in solving the crises. The existence of character traits has been called into question by referring to, for example, Milgram experiments and Philip Zimbardo's Stanford prison experiments that can be interpreted to undercut the thesis that humans have a character, which forms a firm basis for their actions presupposed by classical Aristotelic-Thomistic theory. In these experiments, the test subjects showed very weak ability to resist immoral authorities or the temptation to mistreat others when there were no sanctions for such actions. It therefore seems that humans are easy to manipulate and they conform effortlessly to their surroundings and there is no inherent character or habit that can prevent this. The real life, non-staged, situations that have been subject of much debate include the actions of execution groups during the holocaust and the torture of prisoners in Abu Ghraib after the Second Gulf War. From this point of view, the talk about virtues is not very effective because when things get serious the people do not generally act very virtuously or that moral excellence is possible only for a select few.

Becoming More Virtuous?

However, some studies in psychology suggest that it is possible to train oneself in virtues but this is very energy and time consuming (Slyke et al. 2012; Thiele 2006). The reason for this is that our cognitive machinery constrains our abilities to achieve excellence.

In ► [cognitive psychology](#), it is common to talk about *dual-process models* of cognition, according to which there are two fundamentally different information processing strategies in human cognition: *reflection* and *intuition*. The evidence for the dual-process model of cognition comes from many different sources of which the most important are developmental studies and the study of practical rationality and cognitive biases. Generally, reflection is quite rare in information processing and requires enormous amounts of time and effort. In everyday situations, we automatically trust our intuitions. This means that we automatically acquire and process information in different ways all the time and the information acquired triggers beliefs and actions without any conscious effort. Additionally, due to our brain structure, our first responses to perception are emotional and subconscious, whereas the deliberation takes place only after the initial, fast response. Virtuous reasoning, however, entails that evidence and inference is transparent to the epistemic subject and claims are treated conscientiously. In intuitive thinking, we are driven by factors that are mostly out of our conscious reach. Thus, it seems that we are not designed to act virtuously in all possible cases since our evolutionary history favors conscientiousness only as a means to survival, not as a value per se.

In Plato's *Meno and Protagoras*, it is asked: Can virtue be taught? The answer depends on our understanding of **personhood* as having ability to ground stable dispositions. Pessimistic view, which is usually linked with **eliminativism*, denies the existence of **self* and personhood that could function as the conscious the enduring basis of our actions. In this view, the language of virtue is used mainly as a term of convenience, while the only facts of the matter are the ways how people survive optimally in certain contexts. In this approach, the focus of interest is not in the agent but in the environment in which the agent is situated. Such a view does face the challenge, however, of accounting for the common sense view that we judge persons and not just actions of environments as being "good" or "bad". No one denies that environment has

a great effect to human behavior, and, as already noted, some contexts can effectively thwart virtuous behavior. However, drawing a conclusion that there is no such thing as personhood or self, based on these studies and neuroscientific reflections about the locus of the self, is not necessarily warranted. In addition, the behavioral patterns that erase the notion of the self are usually hazardous for people. In order to lead meaningful lives, we need to presuppose such elementary things as freedom and responsibility, and virtues can be seen as ideal instantiations of these forms of action.

Virtues require much more than being exposed to beneficial theories and impulses, namely, repeated exercise. The results of ► [neuroscience](#) show that repetition strengthens the neural connections in areas that are constantly put in use. This way neuroscience can help us give additional information why, for example, recovering from addictions is so hard: our destructive habits have been engraved in our brain. Naturally, this works other way around as well.

In conclusion, as well as being one of the oldest and fundamental ideas in ethics in antiquity and mediaeval times, virtues have once again become a central theme in philosophy and moral theory. Furthermore, the new developments in neuroscience hold promise for a notable renaissance in the future.

Virtue Ethics

Carl Raschke¹ and Joshua Ramos²

¹Department of Religious Studies, University of Denver, Denver, CO, USA

²University of Denver, Denver, CO, USA

Aristotelian Ethics

Virtue ethics is a branch of normative, or “deontological,” ethics – a subdivision of ethics as a whole, which is a special field of philosophy. Virtue ethics distinguishes itself from the other main sectors of deontological ethics as well as utilitarian, or “consequentialist” ethics, by its concern with the moral character of a person, rather than with one’s action. It is wrong, however, to assume that virtue ethics is not at all interested in actions, as some of its critics have often charged. Virtue ethics seeks rather to understand the teleological or purposeful content of what we do. It presupposes that any action, which stems from desire, is always aimed at an end, and that this end will result in the eventual formation of our moral character and identity. The central question in virtue ethics is that of “who am I?” As Alasdair MacIntyre, the leading contemporary exponent and popularizer of virtue ethics, has put it, virtue ethics asks these key questions: “Who are you? Who are you becoming? How are we to get there?”

Virtue ethics begins with a fundamental discernment into “who you are.” To answer such a question, you must understand yourself first and foremost in order to figure out where your character resides and where it must then go, its striving toward “excellence” (Greek = *arête*) and “happiness” (*eudaimonia*). The term *eudaimonia* also means “well-being,” or “good fortune.” In Aristotelian ethics, *eudaimonia* is the supreme aim of life, the “highest good” or summum bonum. The importance of self-knowledge within the tradition of virtue ethics begins with the Socrates’ maxim of “know yourself” as well as his famous remark that “the unexamined life is not worth living.”

The premier question of virtue ethics can also be phrased as “how ought (generally speaking) I to conduct myself as a person?” But it also remains the case that “ought” is not to be regarded as the imposition of duty or obligation, as is contained in Immanuel Kant’s categorical imperative or in the utilitarian rule of the greatest good for the greatest number of people (Jeremy Bentham). Moral philosophies of both the Kantian and the Benthamian type dominate modern normative ethics. Yet their common emphasis on moral obligation, their assumption that one is constrained to obey a “command of reason” (Kant) or make proper decisions according to what Bentham refers to as a “felicific calculus” of maximum consequential utility in one’s actions, is problematic so far as virtue ethics is concerned. Indeed, it can be said that the difficulty with modern ethics since Kant is that it turns out simply to be a secularized variant of the Judeo-Christian tradition, locating morality in the commands of a Divine lawgiver. With the loss of this Divine giver of law, the trouble is locating the reason “why” one “ought” to be obliged to the categorical imperative or utilitarian principle.

Besides the loss of an ultimate, transcendental “why,” there is also the issue of “universalism” in modern ethics. Critics of virtue ethics charge it with going with the flow of fashionable relativism, since there is no final touchstone against which its outcomes can be measured. But that accusation has also been leveled against Kantian

ethics, which often has a hard time specifying concretely what would be a “universal” rule of action in a given case. Virtue ethics, on the other hand, does not pretend to be rationality but only about desire, character, and the good life. The intent of virtue ethics is the achievement of *eudaimonia* through virtuous living, which was the primary concern of the ancient Greeks. Virtue ethics seems to recapture in modern form the classical ideal.

Besides *arête*, such an ethics concentrates on classical “table of virtues,” especially justice prudence, temperance, and fortitude. Within this listing, prudence is the highest virtue, inasmuch as it regulates the means by which one achieves excellence throughout their character. In addition, for classical thought, there is a unity to the virtues. Each virtue bears relation to each other. Socrates held that there was not many virtues, but only one, that is, *sophia* or wisdom. All the other virtues are variants. Plato held that there are several virtues united by the virtue of justice, whereas Aristotle contended that the many virtues are united by prudence.

Virtue ethics finally gives special attention to *eudaimonia*, for which still other translations is are “well-being” and “good fortune.” *Eudaimonia* is striving for the highest good, the *summum bonum*, as it was called in Medieval philosophy. The ancient Greek poets and playwrights understood *eudaimonia* as a blessed state conferred by fate, or the gods, and thus was the lot not of the many, but of only the few. The philosophers attempted to wrest away the strength of fate, fortune, luck, or chance to one’s state of well-being, and posited that *eudaimonia* was mostly a matter of choice. It is the choices we make, which become the habits that form our character, that make it possible eventually to achieve happiness, or the good life. *Eudaimonia* means living a life that is meaningful and fulfilled. There is no exact rule, commandment, or formula to reach this goal. As Aristotle observes in the *Nicomachean Ethics*, there can never be precision in ethical decision-making.

Aristotle draws a careful distinction between intellectual and character virtues. And he gives

priority to the former. Socrates believes that all desires are rational, because they possess within themselves reasons (*aitia*). Therefore, knowledge and ignorance correspond to virtue and vice, respectively. For the Stoics, what is naturally appropriate to us is desire (*oikeiosis*). Because of our human nature, rational desires seeking our own good are built into human nature, but it is the corruption of this nature that often leads to vice. Christian ethics in late antiquity, especially the thought of St. Paul and St. Augustine, built upon this insight, attributing such corruption not to bad, individual character but the fall and the subsequent degeneracy of the created order.

Virtue ethics, which builds upon both classical pagan and Christian sources of inspiration, dwells on the need to consider the whole of life, not just specific behavior. Our character is rooted in human nature, which includes our natural inclinations and instincts, and our desire for the *summum bonum*, which is some kind of well-being based on making the right decisions and aiming for the higher rather than the lower pleasures. Virtue ethics is both agent-centered and personality-centered. Agent-centered is distinguished from rule-based, law-founded, or calculative decision-making, and typifying de-ontological reasoning. The *eudaimonia* that we seek is first our own personal good. But our personal well-being is intimately bound up with our relations to others. Ethics in the classical sense is inherently situated and pursued within the context of a responsible community, within a *polis*.

Although what we now call “virtue ethics” was the dominant strand of discourse in moral philosophy up until the eighteenth century, it fell out of favor after Kant. The revival of virtue ethics in the contemporary context can be traced to an article published by Irish philosopher G.E. Anscombe entitled “Modern Moral Philosophy” in 1958. The piece is credited with bringing virtue ethics back to life as well as coining the term “consequentialism,” which is now a stock part of the vocabulary of virtue ethics. She argued that Kantian preoccupation with moral laws and commands has stirred up a hornet’s nest of conceptual problems in philosophy, and proposed

a return to Aristotle and his central concern for character and virtue. In the 1980s, Alastair MacIntyre, another prominent British philosopher, carried Anscombe's argument forward in his seminal book *After Virtue*, in which he called on the carpet the liberal philosophy of Enlightenment, resorting ironically to Nietzsche, who had been ignored in ethics until then.

MacIntyre found modern precept-grounded (deontological) and rule-or-outcomes-based ethics severely deficient because it avoided themes that had been the center of interest for the ancient Greeks, such as motives, moral character, moral education, moral discernment, and "relational" or "communitarian" issues like friendship, family responsibilities, and civic engagement. Whereas conventional modern ethics has routinely asked the question "what must I do," virtue ethics inquires "how must we live?"

Over the past quarter century, the field of ethics has been transformed by the impact of this line of thinking. In the practical and professional, virtue ethics has had profound effects on health care, economic policy, practical theology, and ecological activism. It has impelled us to recognize that the virtues are more than just mere tendencies or dispositions to particular actions, but deep-reaching habits work in tandem with other formative tendencies. Our character is the totality of values, choices, desires, and strength, and good moral choices are impossible in the absence of sound moral character.

Virtue ethics cannot be considered a science, unless one employs the latter word in the sense that the ancient Greeks meant it – *scientia* = wisdom. On the other hand, one of the chief values of modern science has been exactitude in observation and a concern for the general rule rather than the particular case. Much of modern ethics since Kant, who sought to make moral philosophy compatible with experimental science, has aimed to tailor the method of following certain general rules and making them "universally valid," that is, applicable in all situations. Virtue ethics, as noted above, rejects rule-grounded moral reasoning, a procedure Kant

himself tried to borrow from Newtonian physics. Although the "ends" of human life may be universal and consistent for what Kant termed "all rational being," virtue ethics emphasizes the cultivation of personal character in ways that are appropriate to one's own life circumstances. Kant himself, fearful that so-called eudaimonism would inevitably lead to morally inconsistent and subjective decision-making, stressed instead the importance of the "formal" principles operative in our actions, whether they lead to happiness or not.

At the same time, virtue ethics is not, and does not rely on, a religious world view of any kind. On the contrary, virtue ethics is founded on the ancient, naturalistic standpoint that human beings are, as Aristotle said, "rational animals," and that reason unaided by any religious guidance or mystical or supernatural illumination is capable of achieving and fulfilling our true desires as finite creatures. Virtue ethics is preeminently a practical philosophy that draws on the traditions of classical wisdom and the situation insights of trained professionals in today's world.

Voluntary Movement

Giacomo Rizzolatti and Maria Alessandra Umiltà
Dipartimento di Neuroscienze, Sezione di
Fisiologia, Università di Parma, Parma, Italy

Voluntary movements are manifestations of a centrally generated intention to act. The way in which intention is generated is irrelevant for the notion of voluntary movement. It may result from bodily needs such as hunger or thirst, or from higher order deliberations based on one's own beliefs and desires. What counts for voluntary movements is that the individual has a goal and that this goal determines movements leading to its achievement. Unlike for reflexes, in voluntary behavior stimuli do not determine a motor response, they only *set the occasion* for it. According to their needs, animals may or may not respond to the same stimulus.

Walkthrough

Linda Sherrell
Department of Computer Science,
The University of Memphis, Memphis, TN, USA

Similar to an inspection, a walkthrough is a review conducted by four to six individuals. When teams use a waterfall model or one of its adaptations, the members of the team are as follows: a developer from the current phase, a representative from the next phase, a client representative, and a member of the software quality assurance (SQA) group. Note that a small company may not have dedicated SQA personnel.

A walkthrough can be conducted for any software artifact, such as requirements, design documents, or code. Unlike an inspection, a walkthrough has only two steps:

1. Preparation. Each participant of the walkthrough compiles two lists: (1) a list of likely faults and (2) a list of items that are unclear.
2. Walkthrough meeting. The meeting should be chaired by the individual from SQA. The purpose of the meeting is to find faults; they will be corrected later.

Note: See also ► [Inspection](#).

Waterfall Model

Linda Sherrell
Department of Computer Science, The
University of Memphis, Memphis, TN, USA

The Waterfall Model is a software development life cycle model that was originally defined by Royce around 1970. This model has the advantage of dividing the life cycle into phases that are easily understood by management. The phases follow:

- Requirements (the needs of the customer are collected).
- Specification (a formal document containing the requirements is constructed).
- Design
 - Architectural – the modules for the program are specified.
 - Detailed Design – the algorithms and the data structures are defined.
- Implementation (coding is completed).
- Unit Testing (the components are tested individually).
- Integration Testing (the components are combined and tested).
- Post-delivery Maintenance (corrections or enhancements are made to the code).
- Retirement (the code can no longer be maintained or is obsolete so it is removed from service) ([Fig. 1](#)).

Waterfall Model,
Fig. 1 A modern waterfall
model (Adapted from
Schach 2007)

Note: A more modern Waterfall Model has feedback loops to the previous phases, because faults may be found during development, or the customer may change the requirements necessitating a return to a previous phase. In some renderings of the model, the testing phases are removed, since testing (reviews in early phases or execution of code in latter phases) should occur throughout the life cycle model.

Western Psychotherapy

Augustine Nwoye

School of Applied Human Sciences, University of KwaZulu-Natal, Pietermaritzburg, South Africa

In this entry on African psychotherapy, we must clarify its relationship to Western psychotherapy. This is because although African psychotherapy is built on the secure foundations of African indigenous healing systems. As currently practiced it operates as a hybrid science which involves the study and application of the best practices in Western and indigenous psychological therapies to the

amelioration of the psychosocial wounds and damages, and stresses and challenges of the postcolonial Africans and their world. Seen in this way, African psychotherapy encompasses the study of the major theories and perspectives, and the techniques and approaches of individual psychotherapy, family therapy, and systemic practice in both indigenous Africa and the modern West.

Wisdom (Philosophically)

Charles Taliaferro
Department of Philosophy, St. Olaf College,
Northfield, MN, USA

Related Terms

[Reflective judgment and moderate living;](#)
[Theoretical and practical reason](#)

Description

The concept of wisdom lies at the heart of Western philosophy, as the very name “philosophy” is Greek for the love of wisdom. In general, there is a prevalent notion that a wise person is one who has both substantial theoretical and practical knowledge (or reasonable beliefs), as this bears on the conduct of life, and that the wise person actually does indeed live life in light of such knowledge. Merely having the knowledge is compatible with being a fool, because one might know how to live rightly and yet not do so. Traditionally, wise persons have been thought of as humble, moderate in their appetites and desires, and good teachers. Each of these taken alone may not constitute wisdom, as it is possible to be humble and foolish, not wise in one’s

moderation, and one may be a good teacher while not following one’s own teaching. A wise person is often thought of as someone who has an integrated life. They may live in a time of great turmoil, but there is a tradition of thinking that a wise person would have sufficient internal serenity that they may be counted on to find the best ways of addressing bad states of affairs.

Modern Developments

The starting point for some modern theorizing about wisdom is the topic of reason itself. There is a strong desire-based concept of reason that was articulated by David Hume and defended recently by Bernard Williams. In this tradition, reason is very much anchored in what a person desires. If a person desires X (going to the market), then she has a reason to go to market. But on this tradition, if you do not have the relevant desire, you have no reason to go to market. This position is sometimes called “internalism,” for it makes reason rest on what a subject internally desires. The alternative position is often called “externalism,” and its modern defenders include Derek Parfit, but its heritage goes back to Plato and Aristotle. On this view, reason and goodness do not depend on what a subject desires. So, let us imagine that a person has no desire to live; it may still be that such a person has lots of reasons to live (he is loved by his family and friends; he is healthy and has many promising opportunities in the future; and so on). In the West, in general, most philosophers, who have contributed to what might be called the philosophy of wisdom, have been in this second school of thought. Wisdom consists in discerning what kinds of reasons one should recognize and what sorts of desires one should have. One reason for thinking that this latter tradition is more plausible is because internalists seem forced to hold that most wicked people have no reason not to be wicked. So, to take an extreme case, if Hitler desired the extermination of all European Jews, he had a reason to seek out such an *extermination*, and no reason not to. Many philosophers find such a conclusion unacceptable.

While many philosophers who contribute to the philosophy of wisdom tend to favor

externalism, some seek out a middle position that recognizes some ideals that are important to reason which are independent of a subject's current desires. So, it has been proposed that a wise person is someone who will have those desires that she would approve of if she knew all the relevant facts. To take a simple example: a person may rightly claim to desire to drink X, but she does not realize that X is actually a slow-acting poison that will kill her. On this view, it is not wise for her to desire X because she would not desire to do so if she knew what X would do to her. This middle position can also be adopted by externalists who may well claim that knowing all the relevant facts is one element in discovering what a person has the most reason to do.

While there is widespread support for the notion that wisdom involves reflection, there is some reason to not adopt a simple identification of the two. Arguably, sometimes it is not wise to reflect. When, for example, one is in an emergency and action is urgent to avoid a catastrophe, the wise thing may be to not reflect, but simply to act and to make the most of the opportunity available.

The contrary of being wise is being foolish, but one might be neither. A wise person may also seek to appear foolish in order to avoid some harm, just as a foolish person might seek to appear wise in order to attain some perceived good.

There seems broad support that a wise person is not wise simply out of luck. It may be that someone has gained wisdom because they were lucky (perhaps a person survives a shipwreck out of pure, undeserved good fortune and then learns to sail more wisely), but that the exercise of wisdom itself must stem from the wise person's own abilities.

The Classical Tradition

There is a strong tradition in the West and East in philosophy, which is sometimes called the wisdom tradition or the wisdom literature (in Latin referred to as the *sapiential* tradition). This tradition may be found in sacred scriptures, such as the Torah or Hebrew Bible, in the New Testament; the Qur'an; the Analects; and so on,

in which there is practical advice on moderate living and balance. This tradition was often developed in terms of precepts or proverbs and parables. This tradition also includes appeal to exemplars of the wise life, whether it be Abraham, Jesus, Mohammed, the Buddha, and so on.

This wisdom tradition has sometimes been underappreciated in the history of philosophy. Ancient Greco-Roman philosophers were very much concerned with practical advice on how to live one's life wisely. Some of the more active moral thinkers were very popular in their day, such as Cicero, Seneca, Epictetus, Dio Chrysostom, Philo, Marcus Aurelius, and others. But these thinkers are not at the forefront of much contemporary, standard histories of philosophy.

Probably one of the best-known classics in the wisdom tradition is Boethius' the *Consolations of Philosophy* (*Consolatio Philosophiae*) composed in the sixth century. This book is an extended meditation on human, temporal life in light of the eternal, supremely good Creator, God. While contemporary philosophers focus on the central theme of the philosophy of time and God's omniscience, the book itself is largely taken up with warnings about the hollowness of worldly glory, and the dangers of vanity.

Mention of Boethius brings up a broader point. Arguably, the truth of broader worldviews can have an impact on what counts as wisdom. If, for example, Christian theism is true or (whether it is true or not) it is plausible, there is a certain wisdom in reflecting on and taking into account the virtues of a relationship with God. Alternatively, if secular naturalism is true or plausible, it may (especially if secular naturalism is overwhelmingly evident) seem quite foolish to pursue the virtues in theistic traditions (worship, prayer, and the like). And similar points may be raised in connection with Buddhism and other worldviews.

Humility and Arrogance

While humility is not sufficient for wisdom, it does seem that it is a common component of much of the wisdom literature, and so it is worthy of further reflection.

It may be thought that humility consists in a form of self-depreciation or a tendency to underestimate one's powers and accomplishments, but these may be marks more of humiliation or self-hatred or even outright deception, rather than humility per se. On reflection, humility seems to come very close to the concept of proper pride, in which a person has a just or reasonable view of herself, neither exaggerating her virtues or vices. Humility as a wise virtue seems perhaps only distinguished from proper pride insofar as a humble person might be expected to be more wary of when she might (knowingly or unknowingly) be guilty of vanity.

While foolishness does not seem to necessitate arrogance, the vast amount of the wisdom tradition views arrogance as foolish or at least not a sign of wisdom. Both in the classic wisdom literature and today, the paradigm case of not being wise is the person who is so self-possessed that he arrogantly assumes his propriety and power without any thought that he may be mistaken.

Love of Wisdom

An important strand in the wisdom literature, which goes back to Plato but it is evident in sacred scriptures of different traditions as well, is the thesis that wisdom should be pursued wisely. This raises the paradox in Plato's *Meno*. If one does not already know what wisdom is, how can one inquire into wisdom wisely? Perhaps the answer to this quandary is that we inquirers into wisdom have an inchoate ability to identify wisdom when we see it, and we have some predisposition to appreciate that when inquiring into virtue, it is better to do so with humility, an open mind, an effort to listen fairly to different sources, to exercise patience, and so on. At the least, we may see that such inquiry is more likely to lead one to wisdom than if we approach the topic of wisdom with vanity, arrogance, rage, envy, and impatience.

Women in Buddhism

Bhikkhu Anālayo

Center for Buddhist Studies, University of
Hamburg, Hamburg, Germany

Description

Women make up two of the four assemblies of disciples recognized in Buddhist texts: nuns and female lay disciples, being the counterparts to the other two assemblies of monks and male lay disciples. The attitude displayed toward female lay disciples and nuns in Buddhist texts is complex and does not allow for simple unequivocal statements. The complexity of the subject finds its reflection in different hermeneutic approaches evident in the academic study of this subject.

Early generations of scholars studying the textual sources on women in Indian Buddhism

tended to emphasize the freedom that early Buddhism allowed women (e.g., Horner 1930), a tendency still evident among some academics in Buddhist countries. Subsequent writings, often undertaken from a western feminist perspective, tended to focus instead on negative aspects and instances of misogyny in Buddhist texts and traditions (e.g., Wilson 1996). This has recently led to a call for a synthesis that affords a broader perspective (Collett 2009), especially emphasizing the need to engage in comparative studies of the relevant texts in parallel versions preserved by different Buddhist schools so as to employ a more comprehensive textual basis, enabling the detection of possible signs of later interpolations.

According to a taxonomy that has met with considerable approval among scholars, the attitudes toward women in early Buddhist texts can be subsumed under the following headings (Sponberg 1992):

- Soteriological inclusiveness
- Institutional androcentrism
- Ascetic misogyny

The notion of soteriological inclusiveness stands for an attitude prevalent in what appears to be the early textual strata of the Buddhist discourses on women. A central component of this attitude is a clear endorsement of women's ability to reach all of the four stages of awakening recognized in Buddhist thought (Morris and Hardy 1885–1900, IV, 276). A collection of poems by early Buddhist nuns, the *Therīgāthā*, gathers what according to tradition are women's own words expressing the joy of emancipation (Blackstone 1998). These verses by ancient Indian Buddhist are outstanding among the recorded voices of women from any religious tradition.

One discourse indicates that women and men proceed by the same path to liberation (Feer 1884–1898, I, 33); another passage proclaims that without fully awakened nun disciples the Buddha's teaching would be deficient (Trenckner and Chalmers 1888–1896, I, 490). In short, gender does not matter to one whose mind is concentrated and who has insight (Feer 1884–1898, I, 129).

Institutional androcentrism allocates Buddhist nuns in an inferior hierarchical position compared to Buddhist monks and views them as a less fertile field of merit for lay support. Thus, for example, even the most senior nun should pay respect to a junior monk ordained on that very day (Morris and Hardy 1885–1900, IV, 276). Or else, nuns are prohibited from criticizing monks, whereas monks are permitted to criticize nuns.

The apparently felt need to subordinate female monastics to their male counterparts reflects values in ancient Indian society and would have become a prominent concern after the Buddha's demise (Sponberg 1992: 13), when the still fledgling Buddhist order had to struggle for survival among other competing religious groups and traditions. The notion of female inferiority underlying institutional androcentrism would have received backing from the presumably current belief that to be born as a woman is the result of bad karma (► [Karma](#)).

Lack of sufficient support as a result of being considered inferior recipients of gifts must have been an important factor contributing to the disappearance of the order of fully ordained Buddhist nuns from most of South and Southeast Asia, only surviving in China and adjacent countries like Korea and Vietnam. In the Himalayan regions, where Buddhism arrived comparatively late, an order of fully ordained nuns never came into existence.

Thus, in the countries of Theravāda Buddhism, as well as in the Tibetan tradition, until recently the only option for women to live a renunciate life has been to adopt a status situated somewhere between the monastic and the lay, neither wearing traditional monastic robes nor taking the full set of monastic precepts. This, in turn, has inevitably meant lack of official recognition and support.

The prevalent attitude of ascetic misogyny sees the female as signifying desire per se and posing a continuous threat to male monastics wishing to preserve their celibacy. It typically expresses itself in vilifying women for their presumed ability to prey on innocent males to satisfy their sexual desires. An exceptionally harsh example of the tendency to malign women can

be found in a discourse that compares women to snakes, indicating that the two share the same negative qualities (Morris and Hardy 1885–1900, III, 260). This attitude appears to have its roots in pre-Buddhist times, presumably coming to prominence in the Buddhist traditions once in the course of time monasticism had become more cloistered and thus distanced from the outside world (Sponberg 1992: 24).

The assumption that these three tendencies of soteriological inclusiveness, institutional androcentrism, and ascetic misogyny reflect slightly different historical periods – although they would soon have come to be held synchronically in different sections of the Buddhist community – finds support in comparative studies. Thus, the prevalent notion that women by nature are incapable of being a Buddha appears to be the result of later developments (Anālayo 2009). Similarly, the account of the founding of the order of nuns, a tale often cited for its negative attitude toward female renunciation, allows for a considerably more nuanced reading on being subjected to a comparative study of the different extant canonical versions (Anālayo 2011).

Nevertheless, the three attitudes surveyed above have continued to make their impact felt throughout the history of Buddhism. Thus, there appears to be no major difference in this respect in the Mahāyāna traditions, even though the feminine as a symbol acquires a powerful function in certain texts and practices, especially in Tantric traditions.

The same complexity of differing attitudes is still reflected in Buddhism to the present day. Attempts made in the Theravāda tradition to revive the order of fully ordained nuns, and in the Tibetan Vajrayāna traditions to create such an order, have met with resistance. While in Sri Lanka the revival of female monasticism appears to be fairly successful, the situation in Thailand and particularly in Burma is quite different. Similarly, while the Dalai Lama has expressed his open support, an order of fully ordained nuns in the Tibetan tradition has not yet come into existence. Although the Buddhist traditions are in theory committed to a teaching that denies any ultimate validity to discriminations – be it based

on gender, race, or whatever else – the attitude toward women inherited from the past is not easily reconciled with such teachings and the resulting tension is one of the challenges faced by Buddhism in the modern world.

World Religions

Jakub Cigán

Department for the Study of Religions, Faculty of Arts, Masaryk University, Brno, Czech Republic

An ambiguous term that emerged in the nineteenth century in particular theological academic context used for a delineation of Christendom and other religions. Later, the term was employed for other biblical or scriptural religions in opposition to so-called primitive local religions. Currently, the term is used for (1) living religions, (2) major religions with some missionary aims, and (3) religions with a universal appeal transcending particular local and ethnic settings.

Worldview

Katarina Westerlund

Department of Theology, Uppsala University, Uppsala, Sweden

The concept *worldview* usually refers to an interpretation of reality that provides an overarching framework for the constitution of the world or the ► **cosmos**. Various belief systems, religions, ideologies, and science itself are examples of worldviews that contain differing pictures of the world. A worldview is furthermore connected with a particular moment in history.

The concept of worldview is used in two fundamentally different ways. On the one hand, the word can refer to a scientific worldview in which perceptions of the ► **universe** are derived from

scientific theories in such fields as astronomy, physics, and biology. On the other hand, the concept of worldview can be broader and encompass perceptions that override scientific knowledge – including values, perceptions of the human being, life, and the world – that are not possible to test scientifically. This latter, broader use of the concept incorporates attempts to answer or to formulate an attitude toward existential questions and to create meaning with and/or in life.

In the twenty-first century, the momentous and interconnected changes in society, science, and the arts have created a new situation, in which one may wish to use the concept *neo-worldview*. That concept refers to less systematic, more individual, and changing perceptions of the world or the cosmos. These contextual worldviews are an aspect of the postmodern situation in which human beings live. In society, there is no longer one predominant worldview, but many different and sometimes contradictory worldviews. In present-day scholarly work, there is doubt that human beings can obtain conclusive or reliable knowledge of the world. Nonetheless, human beings seem to have a need to create a basic outlook on life. The neo-worldviews popular under such conditions are not to be regarded as fundamentally true and commonly held pictures of the world or the cosmos but rather as personal attempts to find orientation in life.

The concept of worldview is of relatively recent origin. It stems from nineteenth-century idealism and the somewhat later *Lebensphilosophie* tradition. Nineteenth-century philosophers like Hegel and Nietzsche made use of the contemporary term *Weltanschauung* in their discussion of cultural and historical perspectives on the world. Concepts like *Weltanschauung* and worldview became useful tools at the intersection between religion and science as human beings entered the modern world. After the Age of Enlightenment, human beings replaced God as the center of the universe, and in the scientific evolution that followed, the entire base of knowledge was questioned. Knowledge became dependent upon empirical evidence, and a naturalistic or scientific worldview evolved with no need for god(s) or

supernatural forces. The task for science was to unveil the laws of nature that govern everything in the world, and questions about the origin of the course of events were often dismissed as “metaphysics.” The previously relatively homogenous and to a large extent Christian worldview was vigorously questioned. The rise of a new naturalistic picture based on facts prompted theologians to describe Christian faith as an intellectual and intelligible worldview. This devolvement within both science and ► [theology](#) shows that the word “worldview” belongs to the vocabulary of modernity. Consequently, at the turn of the twentieth century, worldviews became popular both in everyday language and in academic discourse.

During the continuing evolution of science, scientific worldviews have changed significantly in response to scientific findings in natural sciences – notably physics, astronomy, and biology. But new knowledge in social sciences and the arts – not least psychological and sociological knowledge – has also challenged dominant worldviews. Both within science, in ► [religious studies](#), and ► [theology](#), there has been a continuous need to adjust worldviews to new scientific findings. One of the most important discoveries that brought about major challenges for religions and for scholars of religions and theology was Darwin’s theory of evolution.

Philosophically, worldviews have been of great interest. In line with the scientific development at the time, philosophy in the nineteenth century and the beginning of the twentieth century was dealing with questions of how to understand and differentiate between ontological or scientific facts and values or value-laden philosophy. Value orientation was not necessarily assigned to the realm of worldviews and fact to science. Thus, philosophers were preoccupied with distinguishing between objective and subjective standpoints, and they stressed that both kinds of standpoint could be brought together in a worldview.

In modernity, there has been a tendency within science to hold onto a scientific worldview – a worldview that not only is built upon the natural and social sciences but is also strictly materialistic. With a broader understanding of the concept

of worldview, other parallel and trend-setting ideologies such as Marxism, existentialism, and liberalism can be described as worldviews. Ideologies like these are materialistic, but, unlike scientific worldviews, they embrace ethical convictions and (to differing extents) perceptions of the meaning of human life.

During the rise of modernity and in the twentieth century, there has been an ongoing conflict between scholars who argue that the only rational worldview to hold is a scientific one (scientism) and others – such as theologians and philosophers – who have stated that science can never provide a worldview but only contribute to the revision of a worldview. Science cannot give explanations to existential questions like who human beings really are nor can it provide orientation in life or ultimate values. It is argued that a strictly scientific worldview is of limited usefulness because it lacks moral and existential relevance.

In the postmodern situation of the twenty-first century, with growing individualism, secularization, and globalization, worldviews tend to be less generalized and broadly shared. When people no longer accede to traditional religions or ideologies, worldviews tend to be more fragmented and transmutable. These neo-worldviews are more individualistic and eclectic, and they also transcend the traditional division between religious and secular worldviews.

The growing need for a concept like neo-worldview is also rooted in the postmodern development within social sciences and the arts, in which grand narratives have lost their legitimacy and where one acknowledges that political, religious, moral, and scientific authorities are contextual and conditioned by a specific history and culture.

Worldviews in a more traditional meaning – as a commonly held and true overarching framework of the cosmos – are met with suspicion. One way of understanding neo-worldviews is as social and linguistically constructed systems of meaning. Language can no longer state true facts or objective values about the world; it has lost its previous metaphysical, epistemological, and moral meaning. Philosophically, this means that there is no distinct division between the subjective

and the objective world because human beings are recognized as part of the world and are continuously constructing meaning in the world and in human life. Traditional worldviews are reduced to self-referential systems (reifications or narratives) fabricated by the human beings in power. The situation can be described as a post-worldview era, with a pluralism so far-reaching that one can no longer speak of a conflict between worldviews, because worldviews can only be in conflict if they compete as rational presentations of the same “world.” In extreme postmodernity, there exists not one world, but as many worlds as there are possible worldviews.

Ever since the emergence of the term worldview and its forerunner *Weltanschauung*, these concepts have been important to theology and religious studies. The articulation of religions as alternatives to scientific and naturalistic worldviews has brought the concept of worldview to the forefront of religious studies and theology, and it remains relevant in the contemporary pluralistic situation. Scholars of religion and theologians have stressed that human beings need an orientation in life and that every human being has a worldview that forms a background to her or his life. The concept of worldview in religious studies and theology has been and is used in a broad manner, including religions, ideologies, and in some respects also individual human beings’ interpretations of life, the world, and the cosmos. A worldview in this contextualized or individualized sense can function as orientation in life in both moral and existential domains. The concept has been fruitful in various analyses of religions as well as secular ideologies. A basic question in relation to a worldview is what is referred to as the fundamental reality. Are God (s), human beings, or nature found at the base of reality? Moreover, analysis of worldviews can seek to elucidate differing views on ethics, epistemology, ontology, teleology, and theories of explanation. Used in this way, the concept has also functioned as a critical tool in revealing inconsistencies, ethically problematic convictions, and irrational or non-intelligible perceptions in worldviews.

From the end of the nineteenth century, there has been a development within religious studies

and theology toward a more individualistic understanding of worldviews. Research has been conducted to describe ordinary people's worldviews. Individual worldviews among a secular population or those of people belonging to different interest groups have been a research focus, together with worldviews projected in literature or in various artistic forms. These neo-worldviews that have arisen, for instance, in interpretations of the world that are ecologically or holistically oriented and in New Age-inspired worldviews, are less systematized and more contextual than traditional religions and ideologies.

Within other areas of the arts and social sciences – notably anthropology, sociology, and psychology – the concept of worldview has played an important role in studies of groups' and individuals' interpretations of the world or the cosmos.

New findings in the fields of biology, neuroscience, and physics in the twenty-first century have also provided new ways of thinking about the relation between human beings and the world that have or will affect scientific and religious worldviews.

Worldviews interact with specific perceptions in history. In premodern times, trust was placed in a general Christian worldview in which facts as well as values were based on God and his revelation. With modernity, the center of the worldview moved to the human being and to science. Human beings were the starting point, and with their own methods, they were seeking knowledge – facts – about the world. In postmodernity, the trust in human objectivity is lost, together with the hope of reliable knowledge of facts and values of the world. But the attention to and interest in worldviews as a central intellectual concept has continued up to the present time. The concept is still used in a variety of scientific and everyday contexts. There is, however, no single scientific discipline that can claim to give an exhausting picture of what exists or comprehensive knowledge of the cosmos. Every assertion

of that kind is a metaphysical rather than a scientific statement.

Human beings continue to interpret reality out of the ways in which they think, live, and experience the world. This ongoing human activity points toward a specific feature in human beings, namely, the need for orientation and meaning in the world. Scientific theories or scientific facts alone could not build worldviews that give human beings moral orientation and existential comfort. Language, myth, religion, science, and history will continue to shape worldviews or neo-worldviews – which will play an important role in human life by creating interpretations of reality and providing orientation and meaning.
